

# Package ‘DataSimilarity’

May 15, 2026

**Type** Package

**Title** Quantifying Similarity of Datasets and Multivariate Two- And k-Sample Testing

**Version** 0.4.0

**Date** 2026-05-15

**Depends** R (>= 3.5.0)

**Imports** boot, stats

**Suggests** ade4, approxOT, Ball, caret, clue, cramer, crossmatch, dbscan, densratio, DWDLargeR, e1071, Ecume, energy, expm, FNN, GraphRankTest, gTests, gTestsMulti, HDLSSkST, hypoRF, kernlab, kerTests, KMD, knitr, LPKsample, Matrix, mvtnorm, nbpMatching, pROC, purrr, randtoolbox, rlemon, rpart, rpart.plot, testthat, nnet, synthpop, igraph, cluster

**Description** A collection of methods for quantifying the similarity of two or more datasets, many of which can be used for two- or k-sample testing. It provides newly implemented methods as well as wrapper functions for existing methods that enable calling many different methods in a unified framework. The methods were selected from the review and comparison of Stolte et al. (2024) <[doi:10.1214/24-SS149](https://doi.org/10.1214/24-SS149)>. An empirical comparison of the methods was performed in Stolte et al. (2026) <[doi:10.48550/arXiv.2604.11458](https://doi.org/10.48550/arXiv.2604.11458)> for categorical data and in Stolte et al. (2026) <[doi:10.48550/arXiv.2604.12327](https://doi.org/10.48550/arXiv.2604.12327)> for numeric data.

**License** GPL (>= 3)

**LazyData** true

**NeedsCompilation** no

DataSimilarity-package

*Quantifying Similarity of Datasets and Multivariate Two- And k-Sample Testing*

---

## Description

A collection of methods for quantifying the similarity of two or more datasets, many of which can be used for two- or k-sample testing. It provides newly implemented methods as well as wrapper functions for existing methods that enable calling many different methods in a unified framework. The methods were selected from the review and comparison of Stolte et al. (2024) <doi:10.1214/24-SS149>. An empirical comparison of the methods was performed in Stolte et al. (2026) <doi:10.48550/arXiv.2604.11458> for categorical data and in Stolte et al. (2026) <doi:10.48550/arXiv.2604.12327> for numeric data.

Bahr

*Bahr (1996) Multivariate Two-sample Test*

---

## Description

The function implements the *Bahr (1996)* multivariate two-sample test. This test is a special case of the rigid-motion invariant multivariate two-sample test of *Baringhaus and Franz (2010)*. The implementation here uses the `cramer.test` implementation from the `cramer` package.

## Usage

```
Bahr(X1, X2, n.perm = 0, just.statistic = n.perm <= 0,
      sim = "ordinary", maxM = 2^14, K = 160, seed = NULL)
```

## Arguments

X1	First dataset as matrix or data.frame
X2	Second dataset as matrix or data.frame
n.perm	Number of permutations for permutation or Bootstrap test, respectively (default: 0, no permutation test performed)
just.statistic	Should only the test statistic be calculated without performing any test (default: TRUE if number of permutations is set to 0 and FALSE if number of permutations is set to any positive number)
sim	Type of Bootstrap or eigenvalue method for testing. Possible options are "ordinary" (default) for ordinary Bootstrap, "permutation" for permutation testing, or "eigenvalue" for bootstrapping the limit distribution (especially good for datasets too large for performing Bootstrapping). For more details see <code>cramer.test</code>
maxM	Maximum number of points used for fast Fourier transform involved in eigenvalue method for approximating the null distribution (default: 2^14). Ignored if sim is either "ordinary" or "permutation". For more details see <code>cramer.test</code> .

K	Upper value up to which the integral for calculating the distribution function from the characteristic function is evaluated (default: 160). Note: when K is increased, it is necessary to also increase maxM. Ignored if sim is either "ordinary" or "permutation". For more details see <a href="#">cramer.test</a> .
seed	Random seed (default: NULL). A random seed will only be set if one is provided.

## Details

The *Bahr (1996)* test is a specialcase of the test of *Bahrinhaus and Franz (2010)*

$$T_{n_1, n_2} = \frac{n_1 n_2}{n_1 + n_2} \left( \frac{2}{n_1 n_2} \sum_{i=1}^{n_1} \sum_{j=1}^{n_2} \phi(\|X_{1i} - X_{2j}\|^2) - \frac{1}{n_1^2} \sum_{i,j=1}^{n_1} \phi(\|X_{1i} - X_{1j}\|^2) - \frac{1}{n_2^2} \sum_{i,j=1}^{n_2} \phi(\|X_{2i} - X_{2j}\|^2) \right)$$

where the kernel function  $\phi$  is set to

$$\phi_{\text{Bahr}}(x) = 1 - \exp(-x/2).$$

The theoretical statistic underlying this test statistic is zero if and only if the distributions coincide. Therefore, low values of the test statistic indicate similarity of the datasets while high values indicate differences between the datasets.

This implementation is a wrapper function around the function [cramer.test](#) that modifies the in- and output of that function to match the other functions provided in this package. For more details see the [cramer.test](#).

## Value

An object of class `htest` with the following components:

method	Description of the test
d	Number of variables in each dataset
m	Sample size of first dataset
n	Sample size of second dataset
statistic	Observed value of the test statistic
p.value	Bootstrap/ permutation p value (only if <code>n.perm &gt; 0</code> )
sim	Type of Bootstrap or eigenvalue method (only if <code>n.perm &gt; 0</code> )
n.perm	Number of permutations for permutation or Bootstrap test
hypdist	Distribution function under the null hypothesis reconstructed via fast Fourier transform. <code>\$x</code> contains the x-values, <code>\$Fx</code> contains the corresponding distribution function values. (only if <code>n.perm &gt; 0</code> )
ev	Eigenvalues and eigenfunctions when using the eigenvalue method (only if <code>n.perm &gt; 0</code> )
data.name	The dataset names
alternative	The alternative hypothesis

## Applicability

Target variable?	Numeric?	Categorical?	K-sample?
No	Yes	No	No

## Note

Because this method cannot handle missing data, any missing values are removed automatically and a warning is issued.

## Examples

```
set.seed(1234)
# Draw some data
X1 <- matrix(rnorm(1000), ncol = 10)
X2 <- matrix(rnorm(1000, mean = 0.5), ncol = 10)
# Perform Bahr test
if(requireNamespace("cramer", quietly = TRUE)) {
  Bahr(X1, X2, n.perm = 100)
}
```

BallDivergence

*Ball Divergence Based Two- or k-sample Test***Description**

The function implements the *Pan et al. (2018)* multivariate two- or  $k$ -sample test based on the Ball Divergence. The implementation here uses the `bd.test` implementation from the **Ball** package.

**Usage**

```
BallDivergence(X1, X2, ..., n.perm = 0, seed = NULL, num.threads = 0,
               kbd.type = "sum", weight = c("constant", "variance"),
               args.bd.test = NULL)
```

**Arguments**

<code>X1</code>	First dataset as matrix or data.frame
<code>X2</code>	Second dataset as matrix or data.frame
<code>...</code>	Optionally more datasets as matrices or data.frames
<code>n.perm</code>	Number of permutations for permutation test (default: 0, no permutation test performed). Note that for more than two samples, no test is performed.
<code>seed</code>	Random seed (default: NULL). A random seed will only be set if one is provided.
<code>num.threads</code>	Number of threads (default: 0, all available cores are used)
<code>kbd.type</code>	Character specifying which $k$ -sample test statistic will be used. Must be one of "sum" (default), "maxsum", or "max".
<code>weight</code>	Character specifying the weight form of the Ball Divergence test statistic. Must be one of "constant" (default) or "variance".
<code>args.bd.test</code>	Further arguments passed to <code>bd.test</code> as a named list.

**Details**

For `n.perm = 0`, the asymptotic test is performed. For `n.perm > 0`, a permutation test is performed.

The Ball Divergence is defined as the square of the measure difference over a given closed ball collection. The empirical test performed here is based on the difference between averages of metric ranks. It is robust to outliers and heavy-tailed data and suitable for imbalanced sample sizes.

The Ball Divergence of two distributions is zero if and only if the distributions coincide. Therefore, low values of the test statistic indicate similarity and the test rejects for large values of the test statistic.

For the  $k$ -sample problem the pairwise Ball divergences can be summarized in different ways. First, one can simply sum up all pairwise Ball divergences (`kbd.type = "sum"`). Next, one can find the sample with the largest difference to the other, i.e. take the maximum of the sums of all Ball divergences for each sample with all other samples (`kbd.type = "maxsum"`). Last, one can sum up the largest  $k - 1$  pairwise Ball divergences (`kbd.type = "max"`).

This implementation is a wrapper function around the function `bd.test` that modifies the in- and output of that function to match the other functions provided in this package. For more details see `bd.test` and `bd`.

## Value

An object of class `htest` with the following components:

<code>statistic</code>	Observed value of the test statistic
<code>p.value</code>	Permutation p value (only if <code>n.perm &gt; 0</code> and for two datasets)
<code>n.perm</code>	Number of permutations for permutation test
<code>size</code>	Number of observations for each dataset
<code>method</code>	Description of the test
<code>data.name</code>	The dataset names
<code>alternative</code>	The alternative hypothesis

## Applicability

Target variable?	Numeric?	Categorical?	K-sample?
No	Yes	No	Yes

## Note

Because this method cannot handle missing data, any missing values are removed automatically and a warning is issued.

```
set.seed(1234)
# Draw some data
X1 <- matrix(rnorm(1000), ncol = 10)
X2 <- matrix(rnorm(1000, mean = 0.5), ncol = 10)
# Calculate Ball Divergence and perform test
if(requireNamespace("Ball", quietly = TRUE)) {
  BallDivergence(X1, X2, n.perm = 100)
}
```

---

BF	<i>Baringhaus and Franz (2010) Rigid Motion Invariant Multivariate Two-sample Test</i>
----	--

---

## Description

The function implements the *Baringhaus and Franz (2010)* multivariate two-sample test. The implementation here uses the `cramer.test` implementation from the `cramer` package.

## Usage

```
BF(X1, X2, n.perm = 0, just.statistic = n.perm <= 0, kernel = "phiFracA",
  sim = "ordinary", maxM = 2^14, K = 160, seed = NULL)
```

## Arguments

X1	First dataset as matrix or data.frame
X2	Second dataset as matrix or data.frame
n.perm	Number of permutations for permutation or Bootstrap test, respectively (default: 0, no permutation test performed)
just.statistic	Should only the test statistic be calculated without performing any test (default: TRUE if number of permutations is set to 0 and FALSE if number of permutations is set to any positive number)
kernel	Name of the kernel function as character. Possible options are "phiLog", "phiFracA" (default), and "phiFracB". Alternatively, a user-defined function can be supplied. The function should allow a matrix as input and fulfill the following properties. The output should be non-negative, the value of 0 should be mapped to 0, and the first derivative should be non-constant completely monotone.
sim	Type of Bootstrap or eigenvalue method for testing. Possible options are "ordinary" (default) for ordinary Bootstrap, "permutation" for permutation testing, or "eigenvalue" for bootstrapping the limit distribution (especially good for datasets too large for performing Bootstrapping). For more details see <code>cramer.test</code>
maxM	Maximum number of points used for fast Fourier transform involved in eigenvalue method for approximating the null distribution (default: 2 <sup>14</sup> ). Ignored if sim is either "ordinary" or "permutation". For more details see <code>cramer.test</code> .

K	Upper value up to which the integral for calculating the distribution function from the characteristic function is evaluated (default: 160). Note: when K is increased, it is necessary to also increase maxM. Ignored if sim is either "ordinary" or "permutation". For more details see <a href="#">cramer.test</a> .
seed	Random seed (default: NULL). A random seed will only be set if one is provided.

## Details

The *Bahrinhaus and Franz (2010)* test statistic

$$T_{n_1, n_2} = \frac{n_1 n_2}{n_1 + n_2} \left( \frac{2}{n_1 n_2} \sum_{i=1}^{n_1} \sum_{j=1}^{n_2} \phi(\|X_{1i} - X_{2j}\|^2) - \frac{1}{n_1^2} \sum_{i,j=1}^{n_1} \phi(\|X_{1i} - X_{1j}\|^2) - \frac{1}{n_2^2} \sum_{i,j=1}^{n_2} \phi(\|X_{2i} - X_{2j}\|^2) \right)$$

is defined using a kernel function  $\phi$ . According to *Baringhaus and Franz (2010)*, a choice recommended preferably for location alternatives is

$$\phi_{\log}(x) = \log(1 + x),$$

two choices recommended preferably for dispersion alternatives are

$$\phi_{\text{FracA}}(x) = 1 - \frac{1}{1 + x}$$

and

$$\phi_{\text{FracB}}(x) = 1 - \frac{1}{(1 + x)^2}.$$

According to the simulation study in *Stolte et al. (2026)*,  $\phi_{\text{FracA}}$  is a good compromise across many alternatives.

The theoretical statistic underlying this test statistic is zero if and only if the distributions coincide. Therefore, low values of the test statistic indicate similarity of the datasets while high values indicate differences between the datasets.

This implementation is a wrapper function around the function [cramer.test](#) that modifies the in- and output of that function to match the other functions provided in this package. For more details see [cramer.test](#).

## Value

An object of class `htest` with the following components:

method	Description of the test
d	Number of variables in each dataset
m	Sample size of first dataset
n	Sample size of second dataset
statistic	Observed value of the test statistic
p.value	Bootstrap/ permutation p value (only if <code>n.perm &gt; 0</code> )
sim	Type of Bootstrap or eigenvalue method (only if <code>n.perm &gt; 0</code> )

n.perm	Number of permutations for permutation or Bootstrap test
hypdist	Distribution function under the null hypothesis reconstructed via fast Fourier transform. \$x contains the x-values, \$Fx contains the corresponding distribution function values. (only if n.perm > 0)
ev	Eigenvalues and eigenfunctions when using the eigenvalue method (only if n.perm > 0)
data.name	The dataset names
alternative	The alternative hypothesis

### Applicability

Target variable?	Numeric?	Categorical?	K-sample?
No	Yes	No	No

### Note

Because this method cannot handle missing data, any missing values are removed automatically and a warning is issued.

### Examples

```
set.seed(1234)
# Draw some data
X1 <- matrix(rnorm(1000), ncol = 10)
X2 <- matrix(rnorm(1000, mean = 0.5), ncol = 10)
# Perform Baringhaus and Franz test
if(requireNamespace("cramer", quietly = TRUE)) {
  BF(X1, X2, n.perm = 100)
  BF(X1, X2, n.perm = 100, kernel = "phiFracA")
  BF(X1, X2, n.perm = 100, kernel = "phiFracB")
}
```

**Description**

The function implements the *Biau and Gyorfı (2005)* two-sample homogeneity test. This test uses the  $L_1$ -distance between two empirical distribution functions restricted to a finite partition.

**Usage**

```
BG(X1, X2, partition = rectPartition, exponent = 0.8, eps = 0.01, seed = NULL, ...)
```

**Arguments**

X1	First dataset as matrix or data.frame
X2	Second dataset as matrix or data.frame of the same sample size as X1
partition	Function that creates a finite partition for the subspace spanned by the two datasets (default: rectPartition, see Details)
exponent	Exponent used in the partition function, should be between 0 and 1 (default: 0.8).
eps	Small threshold to guarantee edge points are included (default: 0.01)
seed	Random seed (default: NULL). A random seed will only be set if one is provided.
...	Further arguments to be passed to the partition function

**Details**

The *Biau and Gyorfı (2005)* two-sample homogeneity test is defined for two datasets of the same sample size.

By default a rectangular partition (`rectPartition`) is being calculated under the assumption of approximately equal cell probabilities. Use the exponent argument to choose the number of elements of the partition  $m_n$  according to the convergence criteria in *Biau and Gyorfı (2005)*. By default choose  $m_n = n^{0.8}$ . See *Stolte et al. (2026)* for a performance comparison of varying exponent values across different scenarios. For each of the  $p$  variables of the datasets, create  $m_n^{1/p} + 1$  cutpoints along the range of both datasets to define the partition, and ensure at least three cutpoints exist per variable (min, max, and one point splitting the data into two bins).

The test statistic is the  $L_1$ -distance between the vectors of the proportions of points falling into each cell of the partition for each dataset. An asymptotic test is performed using a standardized version of the  $L_1$  distance that is approximately standard normally distributed (Corollary to Theorem 2 in *Biau and Gyorfı (2005)*). Low values of the test statistic indicate similarity. Therefore, the test rejects for large values of the test statistic.

Note that the calculation of the rectangular partition becomes infeasible for increasing numbers of variables  $p$ .

**Value**

An object of class `htest` with the following components:

<code>statistic</code>	Observed value of the (asymptotic) test statistic
<code>p.value</code>	p value
<code>method</code>	Description of the test
<code>data.name</code>	The dataset names
<code>alternative</code>	The alternative hypothesis

**Applicability**

Target variable?	Numeric?	Categorical?	K-sample?
No	Yes	No	No

**Note**

Because this method cannot handle missing data, any missing values are removed automatically and a warning is issued. This may lead to an unequal number of observations in the datasets.

```
set.seed(1234)
# Draw some data
X1 <- matrix(rnorm(1000), ncol = 10)
X2 <- matrix(rnorm(1000, mean = 0.5), ncol = 10)
# Perform BG test
BG(X1, X2)
```

**Description**

Performs the *Biswas and Ghosh (2014)* two-sample test for high-dimensional data.

**Usage**

BG2(X1, X2, n.perm = 0, seed = NULL)

**Arguments**

X1	First dataset as matrix or data.frame
X2	Second dataset as matrix or data.frame
n.perm	Number of permutations for permutation test (default: 0, asymptotic test is performed).
seed	Random seed (default: NULL). A random seed will only be set if one is provided.

**Details**

The test is based on comparing the means of the distributions of the within-sample and between-sample distances of both samples. It is intended for the high dimension low sample size (HDLSS) setting and claimed to perform better in this setting than the tests of *Friedman and Rafsky (1979)*, *Schilling (1986)* and *Henze (1988)* and the Cramér test of *Baringhaus and Franz (2004)*.

The statistic is defined as

$$T = \|\hat{\mu}_{DF} - \hat{\mu}_{DG}\|_2^2, \text{ where}$$

$$\hat{\mu}_{DF} = \left[ \hat{\mu}_{FF} = \frac{2}{n_1(n_1 - 1)} \sum_{i=1}^{n_1} \sum_{j=i+1}^{n_1} \|X_{1i} - X_{1j}\|, \hat{\mu}_{FG} = \frac{1}{n_1 n_2} \sum_{i=1}^{n_1} \sum_{j=1}^{n_2} \|X_{1i} - X_{2j}\| \right],$$

$$\hat{\mu}_{DG} = \left[ \hat{\mu}_{FG} = \frac{1}{n_1 n_2} \sum_{i=1}^{n_1} \sum_{j=1}^{n_2} \|X_{1i} - X_{2j}\|, \hat{\mu}_{GG} = \frac{2}{n_2(n_2 - 1)} \sum_{i=1}^{n_2} \sum_{j=i+1}^{n_2} \|X_{2i} - X_{2j}\| \right].$$

For testing, the scaled statistic

$$T^* = \frac{N\hat{\lambda}(1 - \hat{\lambda})}{2\hat{\sigma}_0^2} T \text{ with}$$

$$\hat{\lambda} = \frac{n_1}{N},$$

$$\hat{\sigma}_0^2 = \frac{n_1 S_1 + n_2 S_2}{N}, \text{ where}$$

$$S_1 = \frac{1}{\binom{n_1}{3}} \sum_{1 \leq i < j < k \leq n_1} \|X_{1i} - X_{1j}\| \cdot \|X_{1i} - X_{1k}\| - \hat{\mu}_{FF}^2 \text{ and}$$

$$S_2 = \frac{1}{\binom{n_2}{3}} \sum_{1 \leq i < j < k \leq n_2} \|X_{2i} - X_{2j}\| \cdot \|X_{2i} - X_{2k}\| - \hat{\mu}_{GG}^2$$

is used as it is asymptotically  $\chi_1^2$ -distributed.

In both cases, low values indicate similarity of the datasets. Thus, the test rejects the null hypothesis of equal distributions for large values of the test statistic.

For  $n \cdot \text{perm} > 0$ , a permutation test is conducted. Otherwise, an asymptotic test using the asymptotic distribution of  $T^*$  is performed.

### Value

An object of class `htest` with the following components:

<code>statistic</code>	Observed value of the test statistic
<code>p.value</code>	Asymptotic or permutation p value
<code>alternative</code>	The alternative hypothesis
<code>method</code>	Description of the test
<code>data.name</code>	The dataset names

### Applicability

Target variable?	Numeric?	Categorical?	K-sample?
No	Yes	No	No

### Note

Because this method cannot handle missing data, any missing values are removed automatically and a warning is issued.

# Perform Biswas and Ghosh test
BMG(X1, X2)

```

---

 BMG

*Biswas et al. (2014) Two-sample Runs Test*

---

**Description**

The function implements the *Biswas, Mukhopadhyay and Gosh (2014)* distribution-free two-sample runs test. This test uses a heuristic approach to calculate the shortest Hamilton path between the two datasets using the `HamiltonPath` function. By default the asymptotic version of the test is calculated.

**Usage**

```
BMG(X1, X2, seed = NULL, asymptotic = TRUE)
```

**Arguments**

<code>X1</code>	First dataset as matrix or data.frame
<code>X2</code>	Second dataset as matrix or data.frame
<code>seed</code>	Random seed (default: NULL). A random seed will only be set if one is provided.
<code>asymptotic</code>	Should the asymptotic version of the test be performed (default: TRUE)

**Details**

The test counts the number of edges in the shortest Hamilton path calculated on the pooled sample that connect points from different samples, i.e.

$$T_{m,n} = 1 + \sum_{i=1}^{N-1} U_i,$$

where  $U_i$  is an indicator function with  $U_i = 1$  if the  $i$ th edge connects points from different samples and  $U_i = 0$  otherwise.

For a combined sample size  $N$  smaller or equal to 1030, the exact version of the *Biswas, Mukhopadhyay and Gosh (2014)* test can be calculated. It uses the univariate run statistic (*Wald and Wolfowitz, 1940*) to calculate the test statistic. For  $N$  larger than 1030, the calculation for the exact version breaks.

If an asymptotic test is performed the asymptotic null distribution is given by

$$T_{m,n}^* \sim \mathcal{N}(0, 4\lambda^2(1 - \lambda)^2)$$

where  $T_{m,n}^* = \sqrt{N}(T_{m,n}/N - 2\lambda(1 - \lambda))$  the asymptotic test statistic,  $\lambda = m/N$  and  $m$  is the sample size of the first dataset. Therefore, low absolute values of the asymptotic test statistic indicate similarity of the two datasets whereas high absolute values indicate differences between the datasets.

### Value

An object of class `htest` with the following components:

<code>statistic</code>	Observed value of the test statistic (note: this is not the asymptotic test statistic)
<code>p.value</code>	(asymptotic) p value
<code>method</code>	Description of the test
<code>data.name</code>	The dataset names
<code>alternative</code>	The alternative hypothesis

### Applicability

Target variable?	Numeric?	Categorical?	K-sample?
No	Yes	No	No

### Note

Because this method cannot handle missing data, any missing values are removed automatically and a warning is issued.

BQS

*Barakat et al. (1996) Two-Sample Test*

---

**Description**

Performs the nearest-neighbor-based multivariate two-sample test of *Barakat et al. (1996)*.

**Usage**

```
BQS(X1, X2, dist.fun = stats::dist, n.perm = 0, dist.args = NULL, seed = NULL)
```

**Arguments**

X1	First dataset as matrix or data.frame
X2	Second dataset as matrix or data.frame
dist.fun	Function for calculating a distance matrix on the pooled dataset (default: <code>stats::dist</code> , Euclidean distance).
n.perm	Number of permutations for permutation test (default: 0, no test is performed).
dist.args	Named list of further arguments passed to <code>dist.fun</code> (default: <code>NULL</code> ).
seed	Random seed (default: <code>NULL</code> ). A random seed will only be set if one is provided.

**Details**

The test is an extension of the *Schilling (1986)* and *Henze (1988)* neighbor test that bypasses choosing the number of nearest neighbors to consider. The Schilling-Henze test statistic is the proportion of edges connecting points from the same dataset in a K-nearest neighbor graph calculated on the pooled sample (standardized with expectation and SD under the null). *Barakat et al. (1996)* take the weighted sum of the Schilling-Henze test statistics for  $K = 1, \dots, N - 1$ , where  $N$  denotes the pooled sample size.

As for the Schilling-Henze test, low values of the test statistic indicate similarity of the datasets. Thus, the null hypothesis of equal distributions is rejected for high values. A permutation test is performed if `n.perm` is set to a positive number.

**Value**

An object of class `htest` with the following components:

<code>statistic</code>	Observed value of the test statistic
<code>p.value</code>	Permutation p value (if <code>n.perm &gt; 0</code> )
<code>alternative</code>	The alternative hypothesis
<code>method</code>	Description of the test
<code>data.name</code>	The dataset names

**Applicability**

Target variable?	Numeric?	Categorical?	K-sample?
No	Yes	No	No

**Note**

Because this method cannot handle missing data, any missing values are removed automatically and a warning is issued.

C2ST

*Classifier Two-Sample Test***Description**

The function implements the Classifier Two-Sample Test (C2ST) of *Lopez-Paz & Oquab (2017)*. The comparison of multiple ( $\geq 2$ ) samples is also possible. The implementation here uses the `classifier_test` implementation from the **Ecume** package.

**Usage**

```
C2ST(X1, X2, ..., split = 0.7, thresh = 0, classifier = "knn", control = NULL,
      train.args = NULL, seed = NULL)
```

**Arguments**

X1	First dataset as matrix or data.frame
X2	Second dataset as matrix or data.frame
...	Optionally more datasets as matrices or data.frames
split	Proportion of observations used for training
thresh	Value to add to the null hypothesis value (default:0). The null hypothesis tested can be formulated as $H_0 : t = p_0 + \text{thresh}$ , where $t$ denotes the test accuracy of the classifier and $p_0$ is the chance level (proportion of largest dataset in pooled sample).
classifier	Classifier to use during training (default: "knn"). See details for possible options.
control	Control parameters for fitting. See <code>trainControl</code> . Defaults to NULL in which case it is set to <code>caret::trainControl(method = "cv")</code> .
train.args	Further arguments passed to <code>train</code> as a named list.
seed	Random seed (default: NULL). A random seed will only be set if one is provided.

**Details**

The classifier two-sample test works by first combining the datasets into a pooled dataset and creating a target variable with the dataset membership of each observation. The pooled sample is then split into training and test set and a classifier is trained on the training data. The classification accuracy on the test data is then used as a test statistic. If the distributions of the datasets do not differ, the classifier will be unable to distinguish between the datasets and therefore the test accuracy will be close to chance level. The test rejects if the test accuracy is greater than chance level.

All methods available for classification within the **caret** framework can be used as methods. A list of possible models can for example be retrieved via

```
names(caret::getModelInfo())[sapply(caret::getModelInfo(), function(x) "Classification"
%in% x$type)]
```

Note that in simulation studies of *Lopez-Paz and Oquab (2022)* and *Stolte et al. (2026)*, the neural net classifier performed better than the k-NN. See below for an example of changing the classifier accordingly.

This implementation is a wrapper function around the function `classifier_test` that modifies the in- and output of that function to match the other functions provided in this package. For more details see the `classifier_test`.

Note that in case of imbalanced sample sizes, the larger datasets are downsampled to match the size of the smallest dataset.

## Value

An object of class `htest` with the following components:

<code>statistic</code>	Observed value of the test statistic
<code>p.value</code>	Asymptotic p value
<code>alternative</code>	The alternative hypothesis
<code>method</code>	Description of the test
<code>data.name</code>	The dataset names
<code>classifier</code>	Chosen classification method

## Applicability

Target variable?	Numeric?	Categorical?	K-sample?
No	Yes	Yes	Yes

## Note

Because this method cannot handle missing data, any missing values are removed automatically and a warning is issued.

CCS

*Weighted Edge-Count Two-Sample Test***Description**

Performs the weighted edge-count two-sample test for multivariate data proposed by *Chen, Chen and Su (2018)*. The test is intended for comparing two samples with unequal sample sizes. The implementation here uses the [g.tests](#) implementation from the **gTests** package.

**Usage**

```

CCS(X1, X2, dist.fun = stats::dist, graph.fun = MST5, n.perm = 0,
    dist.args = NULL, graph.args = NULL, seed = NULL)

```

**Arguments**

X1	First dataset as matrix or data.frame
X2	Second dataset as matrix or data.frame
dist.fun	Function for calculating a distance matrix on the pooled dataset (default: <a href="#">stats::dist</a> , Euclidean distance).
graph.fun	Function for calculating a similarity graph using the distance matrix on the pooled sample (default: <a href="#">MST5</a> , 5-Minimum Spanning Tree).
n.perm	Number of permutations for permutation test (default: 0, asymptotic test is performed).
dist.args	Named list of further arguments passed to <code>dist.fun</code> (default: NULL).

<code>graph.args</code>	Named list of further arguments passed to <code>graph.fun</code> (default: <code>NULL</code> ).
<code>seed</code>	Random seed (default: <code>NULL</code> ). A random seed will only be set if one is provided.

### Details

The test is an enhancement of the Friedman-Rafsky test (original edge-count test) that aims at improving the test's power for unequal sample sizes by weighting. The test statistic is given as

$$Z_w = \frac{R_w - E_{H_0}(R_w)}{\sqrt{\text{Var}_{H_0}(R_w)}}, \text{ where}$$

$$R_w = \frac{n_1}{n_1 + n_2} R_1 + \frac{n_2}{n_1 + n_2} R_2$$

and  $R_1$  and  $R_2$  denote the number of edges in the similarity graph connecting points within the first and second sample  $X_1$  and  $X_2$ , respectively.

High values of the test statistic indicate dissimilarity of the datasets as the number of edges connecting points within the same sample is high meaning that points are more similar within the datasets than between the datasets.

For `n.perm = 0`, an asymptotic test using the asymptotic normal approximation of the null distribution is performed. For `n.perm > 0`, a permutation test is performed.

This implementation is a wrapper function around the function `g.tests` that modifies the in- and output of that function to match the other functions provided in this package. For more details see the `g.tests`.

The chosen defaults are based on the simulation results of *Stolte et al. (2026)*.

### Value

An object of class `htest` with the following components:

<code>statistic</code>	Observed value of the test statistic
<code>p.value</code>	Asymptotic or permutation p value
<code>alternative</code>	The alternative hypothesis
<code>method</code>	Description of the test
<code>data.name</code>	The dataset names

### Applicability

Target variable?	Numeric?	Categorical?	K-sample?
No	Yes	No	No

### Note

Because this method cannot handle missing data, any missing values are removed automatically and a warning is issued.

}
```

---

CCS\_cat

*Weighted Edge-Count Two-Sample Test for Discrete Data*

---

## Description

Performs the weighted edge-count two-sample test for multivariate data proposed by *Chen, Chen and Su (2018)*. The test is intended for comparing two samples with unequal sample sizes. The implementation here uses the [g.tests](#) implementation from the **gTests** package.

## Usage

```
CCS_cat(X1, X2, dist.fun, agg.type = "u", graph.type = "mstree", K = 5, n.perm = 0,
        seed = NULL)
```

**Arguments**

X1	First dataset as matrix or data.frame
X2	Second dataset as matrix or data.frame
dist.fun	Function for calculating the distance of the unique observations. Should take a dataset of the same format as X1 or X2 as its input and return a distance matrix of the pairwise distances in that dataset. Should be appropriate for handling the scale level of the variables present in X1 and X2, e.g. <code>hammingDist</code> for nominal variables, appropriate distances for ordinal data or the Gower distance for mixed nominal and ordinal data.
agg.type	Character giving the method for aggregating over possible similarity graphs. Options are "u" for union of possible similarity graphs (default) and "a" for averaging over test statistics calculated on possible similarity graphs.
graph.type	Character specifying which similarity graph to use. Possible options are "mstree" (default, Minimum Spanning Tree) and "nnlink" (Nearest Neighbor Graph).
K	Parameter for graph (default: 5). If graph.type = "mstree", a K-MST is constructed (K=1 is the classical MST). If graph.type = "nnlink", K gives the number of neighbors considered in the K-NN graph.
n.perm	Number of permutations for permutation test (default: 0, asymptotic test is performed).
seed	Random seed (default: NULL). A random seed will only be set if one is provided.

**Details**

The test is an enhancement of the Friedman-Rafsky test (original edge-count test) that aims at improving the test's power for unequal sample sizes by weighting. The test statistic is given as

$$Z_w = \frac{R_w - E_{H_0}(R_w)}{\sqrt{\text{Var}_{H_0}(R_w)}}, \text{ where}$$

$$R_w = \frac{n_1}{n_1 + n_2} R_1 + \frac{n_2}{n_1 + n_2} R_2$$

and  $R_1$  and  $R_2$  denote the number of edges in the similarity graph connecting points within the first and second sample  $X_1$  and  $X_2$ , respectively. For discrete data, the similarity graph used in the test is not necessarily unique. This can be solved by either taking a union of all optimal similarity graphs or averaging the test statistics over all optimal similarity graphs. For details, see *Zhang and Chen (2022)*.

For  $n.\text{perm} = 0$ , an asymptotic test using the asymptotic normal approximation of the null distribution is performed. For  $n.\text{perm} > 0$ , a permutation test is performed.

The chosen defaults are based on the simulation results of *Stolte et al. (2026)*.

This implementation is a wrapper function around the function `g.tests` that modifies the in- and output of that function to match the other functions provided in this package. For more details see the `g.tests`.

**Value**

An object of class `htest` with the following components:

<code>statistic</code>	Observed value of the test statistic
<code>p.value</code>	Asymptotic or permutation p value
<code>alternative</code>	The alternative hypothesis
<code>method</code>	Description of the test
<code>data.name</code>	The dataset names

**Applicability**

Target variable?	Numeric?	Categorical?	K-sample?
No	No	Yes	No

**Note**

Because this method cannot handle missing data, any missing values are removed automatically and a warning is issued.

}
```

CF

*Generalized Edge-Count Test*

## Description

Performs the generalized edge-count two-sample test for multivariate data proposed by *Chen and Friedman (2017)*. The implementation here uses the `g.tests` implementation from the `gTests` package.

## Usage

```
CF(X1, X2, dist.fun = stats::dist, graph.fun = MST5, n.perm = 0,
  dist.args = NULL, graph.args = NULL, seed = NULL)
```

## Arguments

X1	First dataset as matrix or data.frame
X2	Second dataset as matrix or data.frame
dist.fun	Function for calculating a distance matrix on the pooled dataset (default: <code>stats::dist</code> , Euclidean distance).
graph.fun	Function for calculating a similarity graph using the distance matrix on the pooled sample (default: <code>MST5</code> , 5-Minimum Spanning Tree).
n.perm	Number of permutations for permutation test (default: 0, asymptotic test is performed).
dist.args	Named list of further arguments passed to <code>dist.fun</code> (default: NULL).
graph.args	Named list of further arguments passed to <code>graph.fun</code> (default: NULL).
seed	Random seed (default: NULL). A random seed will only be set if one is provided.

## Details

The test is an enhancement of the Friedman-Rafsky test (original edge-count test) that aims at detecting both location and scale alternatives. The test statistic is given as

$$S = (R_1 - \mu_1, R_2 - \mu_2) \Sigma^{-1} \begin{pmatrix} R_1 - \mu_1 \\ R_2 - \mu_2 \end{pmatrix}, \text{ where}$$

$R_1$  and  $R_2$  denote the number of edges in the similarity graph connecting points within the first and second sample  $X_1$  and  $X_2$ , respectively,  $\mu_1 = E_{H_0}(R_1)$ ,  $\mu_2 = E_{H_0}(R_2)$  and  $\Sigma$  is the covariance matrix of  $R_1$  and  $R_2$  under the null.

High values of the test statistic indicate dissimilarity of the datasets as the number of edges connecting points within the same sample is high meaning that points are more similar within the datasets than between the datasets.

For  $n.\text{perm} = 0$ , an asymptotic test using the asymptotic  $\chi^2$  approximation of the null distribution is performed. For  $n.\text{perm} > 0$ , a permutation test is performed.

This implementation is a wrapper function around the function `g.tests` that modifies the in- and output of that function to match the other functions provided in this package. For more details see the `g.tests`.

The chosen defaults are based on the simulation results of *Stolte et al. (2026)*.

### Value

An object of class `htest` with the following components:

<code>statistic</code>	Observed value of the test statistic
<code>parameter</code>	Degrees of freedom for $\chi^2$ distribution under $H_0$ (only for asymptotic test)
<code>p.value</code>	Asymptotic or permutation p value
<code>alternative</code>	The alternative hypothesis
<code>method</code>	Description of the test
<code>data.name</code>	The dataset names

### Applicability

Target variable?	Numeric?	Categorical?	K-sample?
No	Yes	No	No

### Note

Because this method cannot handle missing data, any missing values are removed automatically and a warning is issued.

CF\_cat

*Generalized Edge-Count Test for Discrete Data*

---

### Description

Performs the generalized edge-count two-sample test for multivariate data proposed by *Chen and Friedman (2017)*. The implementation here uses the `g.tests` implementation from the `gTests` package.

### Usage

```
CF_cat(X1, X2, dist.fun, agg.type = "u", graph.type = "mstree", K = 5, n.perm = 0,
       seed = NULL)
```

### Arguments

X1	First dataset as matrix or data.frame
X2	Second dataset as matrix or data.frame

dist.fun	Function for calculating the distance of the unique observations. Should take a dataset of the same format as X1 or X2 as its input and return a distance matrix of the pairwise distances in that dataset. Should be appropriate for handling the scale level of the variables present in X1 and X2, e.g. <a href="#">hammingDist</a> for nominal variables, appropriate distances for ordinal data or the Gower distance for mixed nominal and ordinal data.
agg.type	Character giving the method for aggregating over possible similarity graphs. Options are "u" (default) for union of possible similarity graphs and "a" for averaging over test statistics calculated on possible similarity graphs.
graph.type	Character specifying which similarity graph to use. Possible options are "mstree" (default, Minimum Spanning Tree) and "nnlink" (Nearest Neighbor Graph).
K	Parameter for graph (default: 5). If graph.type = "mstree", a K-MST is constructed (K=1 is the classical MST). If graph.type = "nnlink", K gives the number of neighbors considered in the K-NN graph.
n.perm	Number of permutations for permutation test (default: 0, asymptotic test is performed).
seed	Random seed (default: NULL). A random seed will only be set if one is provided.

## Details

The test is an enhancement of the Friedman-Rafsky test (original edge-count test) that aims at detecting both location and scale alternatives. The test statistic is given as

$$S = (R_1 - \mu_1, R_2 - \mu_2) \Sigma^{-1} \begin{pmatrix} R_1 - \mu_1 \\ R_2 - \mu_2 \end{pmatrix}, \text{ where}$$

$R_1$  and  $R_2$  denote the number of edges in the similarity graph connecting points within the first and second sample  $X_1$  and  $X_2$ , respectively,  $\mu_1 = E_{H_0}(R_1)$ ,  $\mu_2 = E_{H_0}(R_2)$  and  $\Sigma$  is the covariance matrix of  $R_1$  and  $R_2$  under the null.

For discrete data, the similarity graph used in the test is not necessarily unique. This can be solved by either taking a union of all optimal similarity graphs or averaging the test statistics over all optimal similarity graphs. For details, see [Zhang and Chen \(2022\)](#).

High values of the test statistic indicate dissimilarity of the datasets as the number of edges connecting points within the same sample is high meaning that points are more similar within the datasets than between the datasets.

For  $n.\text{perm} = 0$ , an asymptotic test using the asymptotic normal approximation of the null distribution is performed. For  $n.\text{perm} > 0$ , a permutation test is performed.

The chosen defaults are based on the simulation results of [Stolte et al. \(2026\)](#).

This implementation is a wrapper function around the function [g.tests](#) that modifies the in- and output of that function to match the other functions provided in this package. For more details see the [g.tests](#).

## Value

An object of class `htest` with the following components:

statistic	Observed value of the test statistic
parameter	Degrees of freedom for $\chi^2$ distribution under $H_0$ (only for asymptotic test)
p.value	Asymptotic or permutation p value
alternative	The alternative hypothesis
method	Description of the test
data.name	The dataset names

### Applicability

Target variable?	Numeric?	Categorical?	K-sample?
No	No	Yes	No

}

```

---

CMDistance

*Constrained Minimum Distance*

---

**Description**

Calculates the Constrained Minimum Distance (*Tatti, 2007*) between two datasets.

**Usage**

```

CMDistance(X1, X2, binary = NULL, cov = FALSE,
           S.fun = function(x) as.numeric(as.character(x)),
           cov.S = NULL, Omega = NULL, seed = NULL)

```

**Arguments**

X1	First dataset as matrix or data.frame
X2	Second dataset as matrix or data.frame
binary	Should the simplified form for binary data be used? (default: NULL, it is checked internally if each variable in the pooled dataset takes on exactly two distinct values)
cov	If the the binary version is used, should covariances in addition to means be used as features? (default: FALSE, corresponds to example 3 in Tatti (2007), TRUE corresponds to example 4). Ignored if binary = FALSE.
S.fun	Feature function (default: NULL). Should be supplied as a function that takes one observation vector as its input. Ignored if binary = TRUE (default: NULL).
cov.S	Covariance matrix of feature function (default: NULL). Ignored if binary = TRUE.
Omega	Sample space as matrix (default: NULL, the sample space is derived from the data internally). Each row represents one value in the sample space. Used for calculating the covariance matrix if cov.S = NULL. Either cov.S or Omega must be given. Ignored if binary = TRUE.
seed	Random seed (default: NULL). A random seed will only be set if one is provided.

**Details**

The constrained minimum (CM) distance is not a distance between distributions but rather a distance based on summaries. These summaries, called frequencies and denoted by  $\theta$ , are averages of feature functions  $S$  taken over the dataset. The constrained minimum distance of two datasets  $X_1$  and  $X_2$  can be calculated as

$$d_{CM}(X_1, X_2|S)^2 = (\theta_1 - \theta_2)^T \text{Cov}^{-1}(S)(\theta_1 - \theta_2),$$

where  $\theta_i = S(X_i)$  is the frequency with respect to the  $i$ -th dataset,  $i = 1, 2$ , and

$$\text{Cov}(S) = \frac{1}{|\Omega|} \sum_{\omega \in \Omega} S(\omega)S(\omega)^T - \left( \frac{1}{|\Omega|} \sum_{\omega \in \Omega} S(\omega) \right) \left( \frac{1}{|\Omega|} \sum_{\omega \in \Omega} S(\omega) \right)^T,$$

where  $\Omega$  denotes the sample space.

Note that the implementation can only handle limited dimensions of the sample space. The error message

```
"Error in rep.int(rep.int(seq_len(nx), rep.int(rep.fac, nx)), orep) : invalid 'times' value"
```

occurs when the sample space becomes too large to enumerate all its elements. In case of binary data and  $S$  chosen as a conjunction or parity function  $T_F$  on a family of itemsets, the calculation of the CMD simplifies to

$$d_{CM}(D_1, D_2|S_F) = 2\|\theta_1 - \theta_2\|_2,$$

where  $\theta_i = T_F(X_i), i = 1, 2$ , as the sample space and covariance matrix are known. In case of more than two categories, either the sample space or the covariance matrix of the feature function must be supplied.

Small values of the CM Distance indicate similarity between the datasets. No test is conducted.

**Value**

An object of class `htest` with the following components:

<code>statistic</code>	Observed value of the CM Distance
<code>alternative</code>	The alternative hypothesis
<code>method</code>	Description of the test
<code>data.name</code>	The dataset names
<code>binary, cov, S.fun, cov.S, Omega</code>	Input parameters

**Applicability**

Target variable?	Numeric?	Categorical?	K-sample?
No	No	Yes	No

**Note**

Note that there is an error in the calculation of the covariance matrix in A.4 Proof of Lemma 8 in Tatti (2007). The correct covariance matrix has the form

$$\text{Cov}[T_{\mathcal{F}}] = 0.25I$$

since

$$\text{Var}[T_A] = \text{E}[T_A^2] - \text{E}[T_A]^2 = 0.5 - 0.5^2 = 0.25$$

following from the correct statement that  $\text{E}[T_A^2] = \text{E}[T_A] = 0.5$ . Therefore, formula (4) changes to

$$d_{CM}(D_1, D_2 | S_{\mathcal{F}}) = 2\|\theta_1 - \theta_2\|_2$$

and the formula in example 3 changes to

$$d_{CM}(D_1, D_2 | S_I) = 2\|\theta_1 - \theta_2\|_2.$$

Our implementation is based on these corrected formulas. If the original formula was used, the results on the same data calculated with the formula for the binary special case and the results calculated with the general formula differ by a factor of  $\sqrt{2}$ .

Because this method cannot handle missing data, any missing values are removed automatically and a warning is issued.

```

Cramer

*Cramér Two-Sample Test***Description**

Performs Two-Sample Cramér Test (*Baringhaus and Franz, 2004*). The implementation here uses the `cramer.test` implementation from the **cramer** package.

**Usage**

```
Cramer(X1, X2, n.perm = 0, just.statistic = (n.perm <= 0), sim = "ordinary",
       maxM = 2^14, K = 160, seed = NULL)
```

**Arguments**

X1	First dataset as matrix or data.frame
X2	Second dataset as matrix or data.frame
n.perm	Number of permutations for permutation or Bootstrap test, respectively (default: 0, no permutation test performed)
just.statistic	Should only the test statistic be calculated without performing any test (default: TRUE if number of permutations is set to 0 and FALSE if number of permutations is set to any positive number)
sim	Type of Bootstrap or eigenvalue method for testing. Possible options are "ordinary" (default) for ordinary Bootstrap, "permutation" for permutation testing, or "eigenvalue" for bootstrapping the limit distribution (especially good for datasets too large for performing Bootstrapping). For more details see <code>cramer.test</code>
maxM	Maximum number of points used for fast Fourier transform involved in eigenvalue method for approximating the null distribution (default: $2^{14}$ ). Ignored if sim is either "ordinary" or "permutation". For more details see <code>cramer::cramer.test</code> .
K	Upper value up to which the integral for calculating the distribution function from the characteristic function is evaluated (default: 160). Note: when K is increased, it is necessary to also increase maxM. Ignored if sim is either "ordinary" or "permutation". For more details see <code>cramer.test</code> .

seed Random seed (default: NULL). A random seed will only be set if one is provided.

### Details

The Cramér test (*Baringhaus and Franz, 2004*) is a specialcase of the test of *Bahrinhaus and Franz (2010)* where the kernel function  $\phi$  is set to

$$\phi_{\text{Cramer}}(x) = \sqrt{x}/2$$

and can be recommended for location alternatives. The test statistic simplifies to

$$T_{n_1, n_2} = \frac{n_1 n_2}{n_1 + n_2} \left( \frac{1}{n_1 n_2} \sum_{i=1}^{n_1} \sum_{j=1}^{n_2} \|X_{1i} - X_{2j}\| - \frac{1}{2n_1^2} \sum_{i,j=1}^{n_1} \|X_{1i} - X_{1j}\| - \frac{1}{2n_2^2} \sum_{i,j=1}^{n_2} \|X_{2i} - X_{2j}\| \right).$$

This is equal to the Energy statistic (*Székely and Rizzo, 2004*).

The theoretical statistic underlying this test statistic is zero if and only if the distributions coincide. Therefore, low values of the test statistic indicate similarity of the datasets while high values indicate differences between the datasets.

This implementation is a wrapper function around the function `cramer.test` that modifies the in- and output of that function to match the other functions provided in this package. For more details see the `cramer.test`.

### Value

An object of class `htest` with the following components:

<code>method</code>	Description of the test
<code>d</code>	Number of variables in each dataset
<code>m</code>	Sample size of first dataset
<code>n</code>	Sample size of second dataset
<code>statistic</code>	Observed value of the test statistic
<code>p.value</code>	Bootstrap/ permutation p value (only if <code>n.perm &gt; 0</code> )
<code>sim</code>	Type of Bootstrap or eigenvalue method (only if <code>n.perm &gt; 0</code> )
<code>n.perm</code>	Number of permutations for permutation or Bootstrap test
<code>hypdist</code>	Distribution function under the null hypothesis reconstructed via fast Fourier transform. <code>\$x</code> contains the x-values, <code>\$Fx</code> contains the corresponding distribution function values. (only if <code>n.perm &gt; 0</code> )
<code>ev</code>	Eigenvalues and eigenfunctions when using the eigenvalue method (only if <code>n.perm &gt; 0</code> )
<code>data.name</code>	The dataset names
<code>alternative</code>	The alternative hypothesis

## Applicability

Target variable?	Numeric?	Categorical?	K-sample?
No	Yes	No	No

## Note

The Cramér test (*Baringhaus and Franz, 2004*) is equivalent to the test based on the Energy statistic (*Székely and Rizzo, 2004*). Because this method cannot handle missing data, any missing values are removed automatically and a warning is issued.

DataSimilarity	<i>Dataset Similarity</i>
----------------	---------------------------

---

### Description

Calculate the similarity of two or more datasets

### Usage

```
DataSimilarity(X1, X2, method, ...)
```

### Arguments

X1	First dataset as matrix or data.frame
X2	Second dataset as matrix or data.frame
method	Name of method for calculating the similarity of the supplied datasets as a character. See Details.
...	Further arguments passed on to method

### Details

The package includes various methods for calculating the similarity of two or more datasets. Appropriate methods for a specific situation can be found using the [findSimilarityMethod](#) function. In the following, the available methods are listed sorted by their applicability to datasets with different characteristics. We differentiate between the number of datasets (two vs. more than two), the type of data (numeric vs. categorical) and the presence of a target variable in each dataset (with vs. without target variable). Typically, this target variable has to be categorical. Methods might be applicable in multiple cases. Then, they are listed once in each case for which they can be used. For the list of methods, see below. For more guidance for choosing a method, see the simulation results in *Stolte et al. (2026)* as well as the short step-by-step procedure demonstrated in the Getting Started vignette.

### Value

Typically an object of class `htest` with the following components:

statistic	Observed value of the test statistic
parameter	Parameter of the null distribution of the test statistic (where applicable)
p.value	Permutation or asymptotic p value (where applicable)
estimate	Sample estimate (where applicable)
alternative	The alternative hypothesis
method	Description of the test
data.name	The dataset names

Further components specific to the method might be included. For details see the help pages of the respective methods.

### Methods for two numeric datasets without target variables

- Bahr** The *Bahr (1996)* two-sample test. Compares two numeric datasets based on inter-point distances, special case of the test of *Bahrinhaus and Franz (2010)* (**BF**).
- BallDivergence** Ball divergence based two- or  $k$ -sample test for numeric datasets. The Ball Divergence is the square of the measure difference over a given closed ball collection.
- BF** The *Bahrinhaus and Franz (2010)* test. Compares two numeric datasets based on inter-point distances using a kernel function. Different kernel functions are tailored to detecting certain alternatives, e.g. shift or scale.
- BG** The *Biau and Gyorfı (2005)* two-sample homogeneity test. Generalization of the Kolmogorov-Smirnov test for multivariate data, uses the  $L_1$ -distance between two empirical distribution functions restricted to a finite partition.
- BG2** The *Biswas and Ghosh (2014)* two-sample test for high-dimensional data. Compares two numeric datasets based on inter-point distances by comparing the means of the distributions of the within-sample and between-sample distances of both samples.
- BMG** The *Biswas, Mukhopadhyay and Gosh (2014)* distribution-free two-sample runs test. Compares two numeric datasets using the Shortest Hamiltonian Path in the pooled sample.
- BQS** The nearest-neighbor-based multivariate two-sample test of *Barakat et al. (1996)*. Modifies the Schilling-Henze nearest neighbor tests (**SH**) such that the number of nearest neighbors does not have to be chosen.
- C2ST** Classifier Two-Sample Test (C2ST) of *Lopez-Paz and Oquab (2017)*. Can be used for multiple samples and categorical data also. Uses the classification accuracy of a classifier that is trained to distinguish between the datasets.
- CCS** Weighted edge-count two-sample test for multivariate data proposed by *Chen, Chen and Su (2018)*. The test is intended for comparing two samples with unequal sample sizes. It is a modification of the graph-based Friedman-Rafsky test **FR**.
- CF** Generalized edge-count two-sample test for multivariate data proposed by *Chen and Friedman (2017)*. The test is intended for better simultaneous detection of shift and scale alternatives. It is a modification of the graph-based Friedman-Rafsky test **FR**.
- Cramer** The Cramér two-sample test (*Baringhaus and Franz, 2004*). Compares two numeric datasets based on inter-point distances, special case of the test of *Bahrinhaus and Franz (2010)* (**BF**), equivalent to the Energy distance **Energy**.
- DiProPerm** Direction Projection Permutation test. Compares two numeric datasets using a linear classifier that distinguishes between the two datasets by projecting all observations onto the normal vector of that classifier and performing a permutation test using a univariate two-sample statistic on these projected scores.
- DISCOB, DISCOF** Energy statistics distance components (DISCO) (*Rizzo and Székely, 2010*). Compares two or more numeric datasets based on a decomposition of the total variance similar to ANOVA but using inter-point distances. **DISCOB** uses the between-sample inter-point distances, **DISCOF** uses an F-type statistic that takes the within- and between-sample inter-point distances into account.
- DS** Multivariate rank-based two-sample test using measure transportation by *Deb and Sen (2021)*. Uses a rank version of the **Energy** statistic.
- Energy** The Energy statistic multi-sample test (*Székely and Rizzo, 2004*). Compares two or more numeric datasets based on inter-point distances. Equivalent to the **Cramer** test.

- engineerMetric** The  $L_q$ -engineer metric for comparing two multivariate distributions.
- FR** The Friedman-Rafsky two-sample test (original edge-count test) for multivariate data (*Friedman and Rafsky, 1979*). Compares two numeric datasets using the number of edges connecting points from different samples in a similarity graph (e.g. MST) on the pooled sample.
- FStest** Modified/ multiscale/ aggregated FS test (*Paul et al., 2021*). Compares two or more datasets in the high dimension low sample size (HDLSS) setting based on a Fisher test for the independence of a clustering of the data and the true dataset membership.
- GPK** Generalized permutation-based kernel two-sample test proposed by *Song and Chen (2021)*. Modification of the **MMD** test intended to better detect differences in variances.
- HMN** Random-forest based two-sample test by *Hediger et al. (2021)*. Uses the (OOB) classification error of a random forest that is trained to distinguish between two datasets. Can also be used with categorical data.
- Jeffreys** Jeffreys divergence. Symmetrized version of the Kullback-Leibler divergence.
- KMD** Kernel measure of multi-sample dissimilarity (KMD) by *Huang and Sen (2023)*. Uses the association between the features and the sample membership to quantify the dissimilarity of the distributions of two or more numeric datasets.
- LHZ** Characteristic distance by *Li et al. (2022)*. Compares two numeric datasets using their empirical characteristic functions.
- MMCM** Multisample Mahalanobis crossmatch (MMCM) test (*Mukherjee et al., 2022*). Uses the optimal non-bipartite matching for comparing two or more numeric or categorical samples. In the two-sample case equivalent to the **Rosenbaum** and to the **Petrie** test.
- MMD** Maximum Mean Discrepancy (MMD). Compares two numeric datasets using a kernel function. Measures the difference between distributions in the reproducing kernel Hilbert space induced by the chosen kernel function.
- MW** Nonparametric graph-based LP (GLP) multisample test proposed by *Mokhopadhyay and Wang (2020)*. Compares two or more numeric datasets based on learning an LP graph kernel using a pre-specified number of LP components and performing clustering on the eigenvectors of the Laplacian matrix for this learned kernel.
- Petrie** *Petrie (2016)* multi-sample cross-match test. Uses the optimal non-bipartite matching for comparing two or more numeric or categorical samples. In the two-sample case equivalent to the **Rosenbaum** and to the **MMCM** test.
- RISE** Rank In Similarity Graph Edge-count two-sample test (RISE) (*Zhou and Chen, 2023*). Compares two datasets in the high dimension using multivariate ranks that are defined based on a similarity graph.
- RItest** Modified/ multiscale/ aggregated RI test (*Paul et al., 2021*). Compares two or more datasets in the high dimension low sample size (HDLSS) setting based on the Rand index of a clustering of the data and the true dataset membership.
- Rosenbaum** *Rosenbaum (2005)* two-sample cross-match test. Uses the optimal non-bipartite matching for comparing two or more numeric or categorical samples. In the two-sample case equivalent to the **Petrie** and to the **MMCM** test.
- SC** Graph-based multi-sample test for high-dimensional data proposed by *Song and Chen (2022)*. Uses the within- and between-sample edge counts in a similarity graph to compare two or more numeric datasets.

- SH** Schilling-Henze nearest neighbor test (*Schilling, 1986; Henze, 1988*). Uses the number of edges connecting points from different samples in a  $K$ -nearest neighbor graph on the pooled sample.
- Wasserstein** Wasserstein distance. Permutation two-sample test for numeric data using the  $p$ -Wasserstein distance.
- YMRZL** Tree-based test of *Yu et al. (2007)*. Uses the classification error of a decision tree trained to distinguish between two datasets. Can also be used with categorical data.
- ZC** Max-type edge-count test (*Zhang and Chen, 2019*). Enhancement of the Friedman-Rafsky test (original edge-count test, **FR**) that aims at detecting both location and scale alternatives and is more flexible than the generalized edge-count test of *Chen and Friedman (2017)* (**CF**).

### Methods for two numeric datasets with target variables

- GGRL** Decision-tree based measure of dataset distance and two-sample test (*Ganti et al., 2002*). Compares the proportions of datapoints of the two datasets falling into each section of the intersection of the partitions induced by fitting a decision tree on each dataset.
- NKT** Decision-tree based measure of dataset similarity by *Ntoutsis et al. (2008)*. Uses density estimates based on the intersection of the partitions induced by fitting a decision tree on each dataset.
- OTDD** Optimal transport dataset distance (OTDD) (*Alvarez-Melis and Fusi, 2020*). The distance combines the distance between features and the distance between label distributions.

### Methods for more than two numeric datasets without target variables

- BallDivergence** Ball divergence based two- or  $k$ -sample test for numeric datasets. The Ball Divergence is the square of the measure difference over a given closed ball collection.
- C2ST** Classifier Two-Sample Test (C2ST) of *Lopez-Paz and Oquab (2017)*. Can be used for multiple samples and categorical data also. Uses the classification accuracy of a classifier that is trained to distinguish between the datasets.
- DISCOB, DISCOF** Energy statistics distance components (DISCO) (*Rizzo and Székely, 2010*). Compares two or more numeric datasets based on a decomposition of the total variance similar to ANOVA but using inter-point distances. **DISCOB** uses the between-sample inter-point distances, **DISCOF** uses an F-type statistic that takes the within- and between-sample inter-point distances into account.
- Energy** The Energy statistic multi-sample test (*Székely and Rizzo, 2004*). Compares two or more numeric datasets based on inter-point distances. Equivalent to the **Cramer** test.
- FStest** Modified/ multiscale/ aggregated FS test (*Paul et al., 2021*). Compares two or more datasets in the high dimension low sample size (HDLSS) setting based on a Fisher test for the independence of a clustering of the data and the true dataset membership.
- KMD** Kernel measure of multi-sample dissimilarity (KMD) by *Huang and Sen (2023)*. Uses the association between the features and the sample membership to quantify the dissimilarity of the distributions of two or more numeric datasets.
- MMCM** Multisample Mahalanobis crossmatch (MMCM) test (*Mukherjee et al., 2022*). Uses the optimal non-bipartite matching for comparing two or more numeric or categorical samples. In the two-sample case equivalent to the **Rosenbaum** and to the **Petrie** test.

- MW** Nonparametric graph-based LP (GLP) multi-sample test proposed by *Mokhopadhyay and Wang (2020)*. Compares two or more numeric datasets based on learning an LP graph kernel using a pre-specified number of LP components and performing clustering on the eigenvectors of the Laplacian matrix for this learned kernel.
- Petrie** *Petrie (2016)* multi-sample cross-match test. Uses the optimal non-bipartite matching for comparing two or more numeric or categorical samples. In the two-sample case equivalent to the **Rosenbaum** and to the **MMCM** test.
- RItest** Modified/ multiscale/ aggregated RI test (*Paul et al., 2021*). Compares two or more datasets in the high dimension low sample size (HDLSS) setting based on the Rand index of a clustering of the data and the true dataset membership.
- SC** Graph-based multi-sample test for high-dimensional data proposed by *Song and Chen (2022)*. Uses the within- and between-sample edge counts in a similarity graph to compare two or more numeric datasets.

### Methods for two categorical datasets without target variables

- C2ST** Classifier Two-Sample Test (C2ST) of *Lopez-Paz and Oquab (2017)*. Can be used for multiple samples and categorical data also. Uses the classification accuracy of a classifier that is trained to distinguish between the datasets.
- CCS\_cat** Weighted edge-count two-sample test for multivariate data proposed by *Chen, Chen and Su (2018)*. The test is intended for comparing two samples with unequal sample sizes. It is a modification of the graph-based Friedman-Rafsky test **FR\_cat**.
- CF\_cat** Generalized edge-count two-sample test for multivariate data proposed by *Chen and Friedman (2017)*. The test is intended for better simultaneous detection of shift and scale alternatives. It is a modification of the graph-based Friedman-Rafsky test **FR\_cat**.
- CMDistance** Constrained Minimum (CM) distance (*Tatti, 2007*). Compares two categorical datasets using the distance of summaries.
- FR\_cat** The Friedman-Rafsky two-sample test (original edge-count test) for multivariate data (*Friedman and Rafsky, 1979*). Compares two numeric datasets using the number of edges connecting points from different samples in a similarity graph (e.g. MST) on the pooled sample.
- HMN** Random-forest based two-sample test by *Hediger et al. (2021)*. Uses the (OOB) classification error of a random forest that is trained to distinguish between two datasets. Can also be used with categorical data.
- MMCM** Multisample Mahalanobis crossmatch (MMCM) test (*Mukherjee et al., 2022*). Uses the optimal non-bipartite matching for comparing two or more numeric or categorical samples. In the two-sample case equivalent to the **Rosenbaum** and to the **Petrie** test.
- Petrie** *Petrie (2016)* multi-sample cross-match test. Uses the optimal non-bipartite matching for comparing two or more numeric or categorical samples. In the two-sample case equivalent to the **Rosenbaum** and to the **MMCM** test.
- YMRZL** Tree-based test of *Yu et al. (2007)*. Uses the classification error of a decision tree trained to distinguish between two datasets. Can also be used with categorical data.
- ZC\_cat** Max-type edge-count test (*Zhang and Chen, 2019*). Enhancement of the Friedman-Rafsky test (original edge-count test, **FR**) that aims at detecting both location and scale alternatives and is more flexible than the generalized edge-count test of Chen and Friedman (2017) (**CF**).

### Methods for two categorical datasets with target variables

- GGRLCat** Decision-tree based measure of dataset distance and two-sample test (*Ganti et al., 2002*). Compares the proportions of datapoints of the two datasets falling into each section of the intersection of the partitions induced by fitting a decision tree on each dataset.
- OTDD** Optimal transport dataset distance (OTDD) (*Alvarez-Melis and Fusi, 2020*). The distance combines the distance between features and the distance between label distributions.

### Methods for more than two categorical datasets without target variables

- C2ST** Classifier Two-Sample Test (C2ST) of *Lopez-Paz and Oquab (2017)*. Can be used for multiple samples and categorical data also. Uses the classification accuracy of a classifier that is trained to distinguish between the datasets.
- MMCM** Multisample Mahalanobis crossmatch (MMCM) test (*Mukherjee et al., 2022*). Uses the optimal non-bipartite matching for comparing two or more numeric or categorical samples. In the two-sample case equivalent to the [Rosenbaum](#) and to the [Petrie](#) test.
- Petrie** *Petrie (2016)* multi-sample cross-match test. Uses the optimal non-bipartite matching for comparing two or more numeric or categorical samples. In the two-sample case equivalent to the [Rosenbaum](#) and to the [MMCM](#) test.

### Methods for two datasets with both categorical and numeric variables but without target variables

- BMG (in case of no ties, appropriate distance function has to be specified)** The *Biswas, Mukhopadhyay and Gosh (2014)* distribution-free two-sample runs test. Compares two numeric datasets using the Shortest Hamiltonian Path in the pooled sample.
- BQS (in case of no ties, appropriate distance function has to be specified)** The nearest-neighbor-based multivariate two-sample test of *Barakat et al. (1996)*. Modifies the Schilling-Henze nearest neighbor tests ([SH](#)) such that the number of nearest neighbors does not have to be chosen.
- C2ST** Classifier Two-Sample Test (C2ST) of *Lopez-Paz and Oquab (2017)*. Can be used for multiple samples and categorical data also. Uses the classification accuracy of a classifier that is trained to distinguish between the datasets.
- CCS (in case of no ties, appropriate distance function has to be specified)** Weighted edge-count two-sample test for multivariate data proposed by *Chen, Chen and Su (2018)*. The test is intended for comparing two samples with unequal sample sizes. It is a modification of the graph-based Friedman-Rafsky test [FR](#).
- CCS\_cat (in case of ties, appropriate distance function has to be specified)** Weighted edge-count two-sample test for multivariate data proposed by *Chen, Chen and Su (2018)*. The test is intended for comparing two samples with unequal sample sizes. It is a modification of the graph-based Friedman-Rafsky test [FR](#).
- CF (in case of no ties, appropriate distance function has to be specified)** Generalized edge-count two-sample test for multivariate data proposed by *Chen and Friedman (2017)*. The test is intended for better simultaneous detection of shift and scale alternatives. It is a modification of the graph-based Friedman-Rafsky test [FR](#).
- CF\_cat (in case of ties, appropriate distance function has to be specified)** Generalized edge-count two-sample test for multivariate data proposed by *Chen and Friedman (2017)*. The test is intended for better simultaneous detection of shift and scale alternatives. It is a modification of the graph-based Friedman-Rafsky test [FR](#).

- FR (in case of no ties, appropriate distance function has to be specified)** The Friedman-Rafsky two-sample test (original edge-count test) for multivariate data (*Friedman and Rafsky, 1979*). Compares two numeric datasets using the number of edges connecting points from different samples in a similarity graph (e.g. MST) on the pooled sample.
- FR\_cat (in case of ties, appropriate distance function has to be specified)** The Friedman-Rafsky two-sample test (original edge-count test) for multivariate data (*Friedman and Rafsky, 1979*). Compares two numeric datasets using the number of edges connecting points from different samples in a similarity graph (e.g. MST) on the pooled sample.
- HMN** Random-forest based two-sample test by *Hediger et al. (2021)*. Uses the (OOB) classification error of a random forest that is trained to distinguish between two datasets. Can also be used with categorical data.
- MMCM (appropriate distance function has to be specified)** Multisample Mahalanobis crossmatch (MMCM) test (*Mukherjee et al., 2022*). Uses the optimal non-bipartite matching for comparing two or more numeric or categorical samples. In the two-sample case equivalent to the [Rosenbaum](#) and to the [Petrie](#) test.
- Petrie (appropriate distance function has to be specified)** *Petrie (2016)* multi-sample cross-match test. Uses the optimal non-bipartite matching for comparing two or more numeric or categorical samples. In the two-sample case equivalent to the [Rosenbaum](#) and to the [MMCM](#) test.
- Rosenbaum (in case of no ties, appropriate distance function has to be specified)** *Rosenbaum (2005)* two-sample cross-match test. Uses the optimal non-bipartite matching for comparing two or more numeric or categorical samples. In the two-sample case equivalent to the [Petrie](#) and to the [MMCM](#) test.
- SC (in case of no ties, appropriate distance function has to be specified)** Graph-based multi-sample test for high-dimensional data proposed by *Song and Chen (2022)*. Uses the within- and between-sample edge counts in a similarity graph to compare two or more numeric datasets.
- SH (in case of no ties, appropriate distance function has to be specified)** Schilling-Henze nearest neighbor test (*Schilling, 1986; Henze, 1988*). Uses the number of edges connecting points from different samples in a  $K$ -nearest neighbor graph on the pooled sample.
- YMRZL** Tree-based test of *Yu et al. (2007)*. Uses the classification error of a decision tree trained to distinguish between two datasets. Can also be used with categorical data.
- ZC (in case of no ties, appropriate distance function has to be specified)** Max-type edge-count test (*Zhang and Chen, 2019*). Enhancement of the Friedman-Rafsky test (original edge-count test, [FR](#)) that aims at detecting both location and scale alternatives and is more flexible than the generalized edge-count test of *Chen and Friedman (2017)* ([CF](#)).
- ZC\_cat (in case of ties, appropriate distance function has to be specified)** Max-type edge-count test (*Zhang and Chen, 2019*). Enhancement of the Friedman-Rafsky test (original edge-count test, [FR](#)) that aims at detecting both location and scale alternatives and is more flexible than the generalized edge-count test of *Chen and Friedman (2017)* ([CF](#)).

#### Methods for two datasets with both categorical and numeric variables and target variables

- OTDD (appropriate distance function has to be specified)** Optimal transport dataset distance (OTDD) (*Alvarez-Melis and Fusi, 2020*). The distance combines the distance between features and the distance between label distributions.

### Methods for more than two datasets with both categorical and numeric variables but without target variables

**C2ST** Classifier Two-Sample Test (C2ST) of *Lopez-Paz and Oquab (2017)*. Can be used for multiple samples and categorical data also. Uses the classification accuracy of a classifier that is trained to distinguish between the datasets.

**MMCM (appropriate distance function has to be specified)** Multisample Mahalanobis crossmatch (MMCM) test (*Mukherjee et al., 2022*). Uses the optimal non-bipartite matching for comparing two or more numeric or categorical samples. In the two-sample case equivalent to the [Rosenbaum](#) and to the [Petrie](#) test.

**Petrie (appropriate distance function has to be specified)** *Petrie (2016)* multi-sample cross-match test. Uses the optimal non-bipartite matching for comparing two or more numeric or categorical samples. In the two-sample case equivalent to the [Rosenbaum](#) and to the [MMCM](#) test.

**SC (in case of no ties, appropriate distance function has to be specified)** Graph-based multi-sample test for high-dimensional data proposed by *Song and Chen (2022)*. Uses the within- and between-sample edge counts in a similarity graph to compare two or more numeric datasets.

dipro.fun

*Direction-Projection Functions for DiProPerm Test*

---

## Description

Helper functions performing the direction and projection step using different classifiers for the Direction-Projection-Permutation (DiProPerm) two-sample test for high-dimensional data (*Wei et al., 2016*)

## Usage

```

dwdProj(X1, X2)
svmProj(X1, X2)

```

## Arguments

X1	First dataset as matrix or data.frame
X2	Second dataset as matrix or data.frame

## Details

The DiProPerm test works by first combining the datasets into a pooled dataset and creating a target variable with the dataset membership of each observation. A binary linear classifier is then trained on the class labels and the normal vector of the separating hyperplane is calculated. The data from both samples is projected onto this normal vector. This gives a scalar score for each observation. On these projection scores, a univariate two-sample statistic is calculated. The permutation null distribution of this statistic is calculated by permuting the dataset labels and repeating the whole procedure with the permuted labels. The functions here correspond to the direction and projection step for either the DWD or SVM classifier as proposed by *Wei et al., 2016*.

The DWD model implementation `genDWD` in the **DWDLargeR** package is used with the penalty parameter  $C$  calculated with `penaltyParameter` using the recommended default values. More details on the algorithm can be found in *Lam et al. (2018)*.

For the SVM, the implementation `svm` in the **e1071** package is used with default parameters.

## Value

A numeric vector containing the projected values for each observation in the pooled sample

```

---

DiProPerm

*Direction-Projection-Permutation (DiProPerm) Test*

---

### Description

Performs the Direction-Projection-Permutation (DiProPerm) two-sample test for high-dimensional data (*Wei et al., 2016*).

### Usage

```

DiProPerm(X1, X2, n.perm = 0, dipro.fun = dwdProj, stat.fun = MD,
          direction = "two.sided", seed = NULL)

```

### Arguments

X1	First dataset as matrix or data.frame
X2	Second dataset as matrix or data.frame
n.perm	Number of permutations for permutation test (default: 0, no permutation test performed)
dipro.fun	Function performing the direction and projection step using a linear classifier. Implemented options are <code>dwdProj</code> (default, distance weighted discrimination, DWD), and <code>svmProj</code> (support vector machine). Must take the two datasets as input and output the calculated scores for the pooled sample.
stat.fun	Function that calculates a univariate two-sample statistic from two vectors. Implemented options are <code>MD</code> (default, mean difference, recommended for detecting mean differences), <code>tStat</code> (t test statistic) and <code>AUC</code> (area under the receiver operating curve). Must take the two numeric vectors as input and output the two sample statistic as a numeric scalar.
direction	Character indicating for which values of the univariate test statistic the test should reject the null hypothesis. Possible options are "two.sided" (reject both for low and high values, appropriate for MD and tStat), "greater" (reject for high values, appropriate for AUC), or "smaller" (reject for low values).
seed	Random seed (default: NULL). A random seed will only be set if one is provided.

### Details

The DiProPerm test works by first combining the datasets into a pooled dataset and creating a target variable with the dataset membership of each observation. A binary linear classifier is then trained on the class labels and the normal vector of the separating hyperplane is calculated. The data from both samples is projected onto this normal vector. This gives a scalar score for each observation.

On these projection scores, a univariate two-sample statistic is calculated. The permutation null distribution of this statistic is calculated by permuting the dataset labels and repeating the whole procedure with the permuted labels.

At the moment, distance weighted discrimination (DWD), and support vector machine (SVM) are implemented as binary linear classifiers.

The DWD model implementation `genDWD` in the **DWDLargeR** package is used with the penalty parameter  $C$  calculated with `penaltyParameter` using the recommended default values. More details on the algorithm can be found in *Lam et al. (2018)*.

For the SVM, the implementation `svm` in the **e1071** package is used with default parameters.

Other classifiers can be used by supplying a suitable function for `dipro.fun`.

For the univariate test statistic, implemented options are the mean difference, t statistic and AUC. Other suitable statistics can be used by supplying a suitable function of `stat.fun`.

The chosen defaults are based on the simulation results of *Stolte et al. (2026)*. See the results there for more detailed results on which linear classifier and univariate statistic to use when.

Whether high or low values of the test statistic correspond to similarity of the datasets depends on the chosen univariate statistic. This is reflected by the `direction` argument which modifies the behavior of the test to reject the null for appropriate values.

## Value

An object of class `htest` with the following components:

<code>statistic</code>	Observed value of the test statistic
<code>p.value</code>	Permutation p value
<code>alternative</code>	The alternative hypothesis
<code>method</code>	Description of the test
<code>data.name</code>	The dataset names

## Applicability

Target variable?	Numeric?	Categorical?	K-sample?
No	Yes	No	No

## Note

Because this method cannot handle missing data, any missing values are removed automatically and a warning is issued.

  }
}
```

**Description**

Performs Energy statistics distance components (DISCO) multi-sample tests (*Rizzo and Székely, 2010*). The implementation here uses the `disco` implementation from the **energy** package.

**Usage**

```
DISCOB(X1, X2, ..., n.perm = 0, alpha = 1, seed = NULL)
```

**Arguments**

X1	First dataset as matrix or data.frame
X2	Second dataset as matrix or data.frame
...	Further datasets as matrices or data.frames
n.perm	Number of permutations for Bootstrap test (default: 0, no Bootstrap test performed)
alpha	Power of the distance used for generalized Energy statistic (default: 1). Has to lie in $(0, 2]$ . For values in $(0, 2)$ , consistency of the resulting test has been shown. <i>Rizzo and Székely (2010)</i> recommend larger values for (close to) normal data and smaller values for heavy-tailed distributions. In <i>Stolte et al. (2026)</i> , good performance for $\alpha = 0.5$ was observed across scenarios but performance generally did not differ much depending on alpha.
seed	Random seed (default: NULL). A random seed will only be set if one is provided.

**Details**

DISCO is a method for multi-sample testing based on all pairwise between-sample distances. It is analogous to the classical ANOVA. Instead of decomposing squared differences from the sample mean, the total dispersion (generalized Energy statistic) is composed into distance components (DISCO) consisting of the within-sample and between-sample measures of dispersion.

DISCOB computes the between-sample DISCO statistic which is the between-sample component.

Small values of the statistic indicate similarity of the datasets and therefore, the null hypothesis of equal distributions is rejected for large values of the statistic.

This implementation is a wrapper function around the function `disco` that modifies the in- and output of that function to match the other functions provided in this package. For more details see the `disco`.

**Value**

An object of class `htest` with the following components:

call	The function call
statistic	Observed value of the test statistic
p.value	Bootstrap p value
alternative	The alternative hypothesis
method	Description of the test
data.name	The dataset names

## Applicability

Target variable?	Numeric?	Categorical?	K-sample?
No	Yes	No	Yes

## Note

Because this method cannot handle missing data, any missing values are removed automatically and a warning is issued.

DISCOF

*Distance Components (DISCO) Tests***Description**

Performs Energy statistics distance components (DISCO) multi-sample tests (*Rizzo and Székely, 2010*). The implementation here uses the `disco` implementation from the `energy` package.

**Usage**

```
DISCOF(X1, X2, ..., n.perm = 0, alpha = 1, seed = NULL)
```

**Arguments**

X1	First dataset as matrix or data.frame
X2	Second dataset as matrix or data.frame
...	Further datasets as matrices or data.frames
n.perm	Number of permutations for Bootstrap test (default: 0, no Bootstrap test performed)
alpha	Power of the distance used for generalized Energy statistic (default: 1). Has to lie in $(0, 2]$ . For values in $(0, 2)$ , consistency of the resulting test has been shown. $\alpha = 2$ is equivalent to ANOVA. <i>Rizzo and Székely (2010)</i> recommend larger values for (close to) normal data and smaller values for heavy-tailed distributions. In <i>Stolte et al. (2026)</i> , good performance for $\alpha = 0.5$ was observed across scenarios but performance generally did not differ much depending on alpha.
seed	Random seed (default: NULL). A random seed will only be set if one is provided.

**Details**

DISCO is a method for multi-sample testing based on all pairwise between-sample distances. It is analogous to the classical ANOVA. Instead of decomposing squared differences from the sample mean, the total dispersion (generalized Energy statistic) is composed into distance components (DISCO) consisting of the within-sample and between-sample measures of dispersion.

DISCOF is based on the DISCO F ratio of the between-sample and within-sample dispersion. Note that the  $F$  ratio does not follow an F distribution, but is just called F ratio analogous to the ANOVA.

In both cases, small values of the statistic indicate similarity of the datasets and therefore, the null hypothesis of equal distributions is rejected for large values of the statistic.

This implementation is a wrapper function around the function `disco` that modifies the in- and output of that function to match the other functions provided in this package. For more details see the `disco`.

**Value**

An object of class `disco` with the following components:

<code>call</code>	The function call
<code>method</code>	Description of the test
<code>statistic</code>	Vector of observed values of the test statistic
<code>p.value</code>	Vector of Bootstrap p values
<code>k</code>	Number of samples
<code>N</code>	Number of observations
<code>between</code>	Between-sample distance components
<code>within</code>	One-way within-sample distance components
<code>within</code>	Within-sample distance component
<code>total</code>	Total dispersion
<code>Df.trt</code>	Degrees of freedom for treatments
<code>Df.e</code>	Degrees of freedom for error
<code>index</code>	Alpha (exponent on distance)
<code>factor.names</code>	Factor names
<code>factor.levels</code>	Factor levels
<code>sample.sizes</code>	Sample sizes
<code>stats</code>	Matrix containing decomposition

**Applicability**

Target variable?	Numeric?	Categorical?	K-sample?
No	Yes	No	Yes

**Note**

Because this method cannot handle missing data, any missing values are removed automatically and a warning is issued.

  DISCOF(X1, X2, n.perm = 100)
}
```

---

 DS

*Rank-Based Energy Test (Deb and Sen, 2021)*

---

### Description

Performs the multivariate rank-based two-sample test using measure transportation by *Deb and Sen (2021)*.

### Usage

```
DS(X1, X2, n.perm = 0, rand.gen = NULL, seed = NULL)
```

### Arguments

X1	First dataset as matrix or data.frame
X2	Second dataset as matrix or data.frame
n.perm	Number of permutations for permutation test (default: 0, no permutation test performed)
rand.gen	Function that generates a grid of (random) numbers in $(0, 1)$ of dimension $n \times k$ ( $n$ and $k$ are inputs of this function). Default is NULL in which case, <a href="#">randtoolbox::halton</a> is used.
seed	Random seed (default: NULL). A random seed will only be set if one is provided.

### Details

The test proposed by *Deb and Sen (2021)* is a rank-based version of the Energy statistic (*Székely and Rizzo, 2004*) that does not rely on any moment assumptions. Its test statistic is the Energy statistic applied to the rank map of both samples. The multivariate ranks are computed using optimal transport with a multivariate uniform distribution as the reference distribution.

For the rank version of the Energy statistic it still holds that the value zero is attained if and only if the two distributions coincide. Therefore, low values of the empirical test statistic indicate similarity between the datasets and the null hypothesis of equal distributions is rejected for large values.

### Value

An object of class `htest` with the following components:

<code>statistic</code>	Observed value of the test statistic
<code>p.value</code>	Permutation p value
<code>alternative</code>	The alternative hypothesis
<code>method</code>	Description of the test
<code>data.name</code>	The dataset names

### Applicability

Target variable?	Numeric?	Categorical?	K-sample?
No	Yes	No	No

### Note

The implementation is a modification of the code supplied by *Deb and Sen (2021)* for the simulation study presented in the original article. It generalizes the implementation and includes small modifications for computation speed.

Because this method cannot handle missing data, any missing values are removed automatically and a warning is issued.

}
```

---

Energy

*Energy Statistic and Test*

---

## Description

Performs the Energy statistic multi-sample test (*Székely and Rizzo, 2004*). The implementation here uses the [eqdist.etest](#) implementation from the **energy** package.

## Usage

```
Energy(X1, X2, ..., n.perm = 0, seed = NULL)
```

## Arguments

X1	First dataset as matrix or data.frame
X2	Second dataset as matrix or data.frame
...	Further datasets as matrices or data.frames
n.perm	Number of permutations for Bootstrap test (default: 0, no Bootstrap test performed)
seed	Random seed (default: NULL). A random seed will only be set if one is provided.

### Details

The Energy statistic (*Székely and Rizzo, 2004*) for two datasets  $X_1$  and  $X_2$  is defined as

$$T_{n_1, n_2} = \frac{n_1 n_2}{n_1 + n_2} \left( \frac{1}{n_1 n_2} \sum_{i=1}^{n_1} \sum_{j=1}^{n_2} \|X_{1i} - X_{2j}\| - \frac{1}{2n_1^2} \sum_{i,j=1}^{n_1} \|X_{1i} - X_{1j}\| - \frac{1}{2n_2^2} \sum_{i,j=1}^{n_2} \|X_{2i} - X_{2j}\| \right).$$

This is equal to the Cramér test statistic (*Baringhaus and Franz, 2004*). The multi-sample version is defined as the sum of the Energy statistics for all pairs of samples.

The population Energy statistic for two distributions is equal to zero if and only if the two distributions coincide. Therefore, small values of the empirical statistic indicate similarity between datasets and the permutation test rejects the null hypothesis of equal distributions for large values.

This implementation is a wrapper function around the function `eqdist.etest` that modifies the in- and output of that function to match the other functions provided in this package. For more details see the `eqdist.etest`.

### Value

An object of class `htest` with the following components:

<code>call</code>	The function call
<code>statistic</code>	Observed value of the test statistic
<code>p.value</code>	Bootstrap p value
<code>alternative</code>	The alternative hypothesis
<code>method</code>	Description of the test
<code>data.name</code>	The dataset names

### Applicability

Target variable?	Numeric?	Categorical?	K-sample?
No	Yes	No	Yes

### Note

The test based on the Energy statistic (*Székely and Rizzo, 2004*) is equivalent to the Cramér test (*Baringhaus and Franz, 2004*).

Because this method cannot handle missing data, any missing values are removed automatically and a warning is issued.

engineerMetric

*Engineer Metric*

---

## Description

The function implements the  $L_q$ -engineer metric for comparing two multivariate distributions.

## Usage

```
engineerMetric(X1, X2, type = "F", seed = NULL)
```

## Arguments

X1	First dataset as matrix or data.frame
X2	Second dataset as matrix or data.frame
type	Character specifying the type of $L_q$ -norm to use. Reasonable options are "0", "o", "1", for the $L_1$ -norm, "I", and "i", for the $L_\infty$ -norm, and "F", "f", "E", "e" (the default) for the $L_2$ -norm (Euclidean norm).
seed	Random seed (default: NULL). A random seed will only be set if one is provided. Method is deterministic, seed is only set for consistency with other methods.

**Details**

The engineer is a primary propability metric that is defined as

$$\text{EN}(X_1, X_2; q) = \left[ \sum_{i=1}^p |\text{E}(X_{1i}) - \text{E}(X_{2i})|^q \right]^{\min(q, 1/q)} \quad \text{with } q > 0,$$

where  $X_{1i}, X_{2i}$  denote the  $i$ th component of the  $p$ -dimensional random vectors  $X_1 \sim F_1$  and  $X_2 \sim F_2$ .

In the implementation, expectations are estimated by column means of the respective datasets.

**Value**

An object of class `htest` with the following components:

<code>method</code>	Description of the test
<code>statistic</code>	Observed value of the test statistic
<code>data.name</code>	The dataset names
<code>method</code>	Description of the test
<code>alternative</code>	The alternative hypothesis

**Applicability**

Target variable?	Numeric?	Categorical?	K-sample?
No	Yes	No	No

**Note**

The seed argument is only included for consistency with other methods. The result of the metric calculation is deterministic.

Because this method cannot handle missing data, any missing values are removed automatically and a warning is issued.

---

findSimilarityMethod *Selection of Appropriate Methods for Quantifying the Similarity of Datasets*

---

**Description**

Find a dataset similarity method for the dataset comparison at hand and display information on suitable methods.

**Usage**

```

findSimilarityMethod(Numeric = FALSE, Categorical = FALSE,
                     Target.Inclusion = FALSE, Multiple.Samples = FALSE,
                     only.names = TRUE, ...)

```

**Arguments**

Numeric	Is it required that the method is applicable to numeric data? (default: FALSE)
Categorical	Is it required that the method is applicable to categorical data? (default: FALSE)
Target.Inclusion	Is it required that the method is applicable to datasets that include a target variable? (default: FALSE)
Multiple.Samples	Is it required that the method is applicable to multiple datasets simultaneously? (default: FALSE)
only.names	Should only the function names be returned? (default: TRUE, only names are returned. Setting this to FALSE returns the whole method table, see <a href="#">method.table</a> )
...	Further criteria that the method should fulfill, see <code>colnames(method.table)</code> . Each criterion can be used as an argument by supplying <code>criterion = TRUE</code> to obtain only methods that fulfill the respective criterion.

**Details**

This function is intended to facilitate finding suitable methods. The criteria that a method should fulfill for the application at hand can be specified and a vector of the function names or the full information on the methods is returned. For a list of all criteria, see the Details vignette. For more details refer to *Stolte et al. (2024)* See the Getting Started vignette for a step-by-step guide for using the function for choosing a method. See the simulation studies cited below for additional guidance for the method choice and the references cited therein for details of the methods.

**Value**

Either a character vector of function names for `only.names = TRUE` or a subset of `method.table` of the selected methods for `only.names = FALSE`.

FR

*Friedman-Rafsky Test***Description**

Performs the Friedman-Rafsky two-sample test (original edge-count test) for multivariate data (*Friedman and Rafsky, 1979*). The implementation here uses the `g.tests` implementation from the `gTests` package.

**Usage**

```
FR(X1, X2, dist.fun = stats::dist, graph.fun = MST5, n.perm = 0,
   dist.args = NULL, graph.args = NULL, seed = NULL)
```

**Arguments**

X1	First dataset as matrix or data.frame
X2	Second dataset as matrix or data.frame
dist.fun	Function for calculating a distance matrix on the pooled dataset (default: <code>stats::dist</code> , Euclidean distance).
graph.fun	Function for calculating a similarity graph using the distance matrix on the pooled sample (default: <code>MST5</code> , 5-Minimum Spanning Tree).
n.perm	Number of permutations for permutation test (default: 0, asymptotic test is performed).
dist.args	Named list of further arguments passed to <code>dist.fun</code> (default: NULL).
graph.args	Named list of further arguments passed to <code>graph.fun</code> (default: NULL).
seed	Random seed (default: NULL). A random seed will only be set if one is provided.

**Details**

The test is a multivariate extension of the univariate Wald Wolfowitz runs test. The test statistic is the number of edges connecting points from different datasets in a minimum spanning tree calculated on the pooled sample (standardized with expectation and SD under the null).

High values of the test statistic indicate similarity of the datasets. Thus, the null hypothesis of equal distributions is rejected for small values.

For `n.perm = 0`, an asymptotic test using the asymptotic normal approximation of the null distribution is performed. For `n.perm > 0`, a permutation test is performed.

This implementation is a wrapper function around the function `g.tests` that modifies the in- and output of that function to match the other functions provided in this package. For more details see the `g.tests`.

The chosen defaults are based on the simulation results of *Stolte et al. (2026)*.

**Value**

An object of class `htest` with the following components:

<code>statistic</code>	Observed value of the test statistic
<code>p.value</code>	Asymptotic or permutation p value
<code>alternative</code>	The alternative hypothesis
<code>method</code>	Description of the test
<code>data.name</code>	The dataset names

**Applicability**

Target variable?	Numeric?	Categorical?	K-sample?
No	Yes	No	No

**Note**

Because this method cannot handle missing data, any missing values are removed automatically and a warning is issued.

  # Using 3-MST
  FR(X1, X2, graph.fun = MST, graph.args = list(K = 3))
}
```

FR\_cat

*Friedman-Rafsky Test for Discrete Data*

## Description

Performs the Friedman-Rafsky two-sample test (original edge-count test) for multivariate data (*Friedman and Rafsky, 1979*). The implementation here uses the [g.tests](#) implementation from the **gTests** package.

## Usage

```
FR_cat(X1, X2, dist.fun, agg.type = "u", graph.type = "mstree", K = 5, n.perm = 0,
       seed = NULL)
```

## Arguments

X1	First dataset as matrix or data.frame
X2	Second dataset as matrix or data.frame
dist.fun	Function for calculating the distance of the unique observations. Should take a dataset of the same format as X1 or X2 as its input and return a distance matrix of the pairwise distances in that dataset. Should be appropriate for handling the scale level of the variables present in X1 and X2, e.g. <a href="#">hammingDist</a> for nominal variables, appropriate distances for ordinal data or the Gower distance for mixed nominal and ordinal data.
agg.type	Character giving the method for aggregating over possible similarity graphs. Options are "u" (default) for union of possible similarity graphs and "a" for averaging over test statistics calculated on possible similarity graphs.
graph.type	Character specifying which similarity graph to use. Possible options are "mstree" (default, Minimum Spanning Tree) and "nnlink" (Nearest Neighbor Graph).
K	Parameter for graph (default: 5). If graph.type = "mstree", a K-MST is constructed (K=1 is the classical MST). If graph.type = "nnlink", K gives the number of neighbors considered in the K-NN graph.

n.perm	Number of permutations for permutation test (default: 0, asymptotic test is performed).
seed	Random seed (default: NULL). A random seed will only be set if one is provided.

### Details

The test is a multivariate extension of the univariate Wald Wolfowitz runs test. The test statistic is the number of edges connecting points from different datasets in a minimum spanning tree calculated on the pooled sample (standardized with expectation and SD under the null). For discrete data, the similarity graph used in the test is not necessarily unique. This can be solved by either taking a union of all optimal similarity graphs or averaging the test statistics over all optimal similarity graphs. For details, see Zhang and Chen (2022).

High values of the test statistic indicate similarity of the datasets. Thus, the null hypothesis of equal distributions is rejected for small values.

For  $n.perm = 0$ , an asymptotic test using the asymptotic normal approximation of the null distribution is performed. For  $n.perm > 0$ , a permutation test is performed.

The chosen defaults are based on the simulation results of *Stolte et al. (2026)*.

This implementation is a wrapper function around the function `g.tests` that modifies the in- and output of that function to match the other functions provided in this package. For more details see the `g.tests`.

### Value

An object of class `htest` with the following components:

statistic	Observed value of the test statistic
parameter	Degrees of freedom for $\chi^2$ distribution under $H_0$ (only for asymptotic test)
p.value	Asymptotic or permutation p value
alternative	The alternative hypothesis
method	Description of the test
data.name	The dataset names

### Applicability

Target variable?	Numeric?	Categorical?	K-sample?
No	No	Yes	No

### Note

Because this method cannot handle missing data, any missing values are removed automatically and a warning is issued.

---

FStest

*Multisample FS Test*

---

## Description

Performs the (modified/ multiscale/ aggregated) FS test (*Paul et al., 2021*). The implementation is based on the [FStest](#), [MTFStest](#), and [AFStest](#) implementations from the **HDLSSkST** package.

## Usage

```
FStest(X1, X2, ..., n.clust, randomization = TRUE, version = "original",
       mult.test = "Holm", kmax = 2 * n.clust, s.psi = 3, s.h = 1,
       lb = 1, n.perm = 1/alpha, alpha = 0.05, seed = NULL)
```

**Arguments**

X1	First dataset as matrix or data.frame
X2	Second dataset as matrix or data.frame
...	Optionally more datasets as matrices or data.frames
n.clust	Number of clusters (only applicable for version = "original").
randomization	Should a randomized test be performed? (default: TRUE, randomized test is performed)
version	Which version of the test should be performed? Possible options are "original" (default) for the FS test, "modified" for the MFS test (number of clusters is estimated), "multiscale" for the MSFS test (all numbers of clusters up to kmax are tried and results are summarized), "aggregated-knw" (all pairwise comparisons are tested with the FS test and results are aggregated), and "aggregated-est" (all pairwise comparisons are tested with the MFS test and results are aggregated).
mult.test	Multiple testing adjustment for AFS test and MSFS test. Possible options are "Holm" (default) and "BenHoch".
kmax	Maximum number of clusters to try for estimating the number of clusters (default: 2*n.clust).
s.psi	Numeric code for function required for calculating the distance for $K$ -means clustering. The value 1 corresponds to $\psi(t) = t^2$ (the default), 2 corresponds to $\psi(t) = 1 - \exp(-t)$ , 3 corresponds to $\psi(t) = 1 - \exp(-t^2)$ , 4 corresponds to $\psi(t) = \log(1 + t)$ , 5 corresponds to $\psi(t) = t$ .
s.h	Numeric code for function required for calculating the distance for $K$ -means clustering. The value 1 corresponds to $h(t) = \sqrt{t}$ (the default), and 2 corresponds to $h(t) = t$ .
lb	Length of smaller vectors into which each observation is partitioned (default: 1).
n.perm	Number of simulations of the test statistic (default: 1/alpha, minimum number required for running the test, set to a higher value for meaningful test results).
alpha	Test level (default: 0.05).
seed	Random seed (default: NULL). A random seed will only be set if one is provided.

**Details**

The tests are intended for the high dimension low sample size (HDLSS) setting. The idea is to cluster the pooled sample using a clustering algorithm that is suitable for the HDLSS setting and then to compare the clustering to the true dataset membership and test for dependence using a generalized Fisher test on the contingency table of clustering and dataset membership. For the original FS test, the number of clusters has to be specified. If no number is specified it is set to the number of samples. This is a reasonable number of clusters in many cases.

However, in some cases, different numbers of clusters might be needed. For example in case of multimodal distributions in the datasets, there might be multiple clusters within each dataset. Therefore, the modified (MFS) test allows to estimate the number of clusters from the data.

In case of a really unclear number of clusters, the multiscale (MSFS) test can be applied which calculates the test for each number of clusters up to `kmax` and then summarizes the test results using some adjustment for multiple testing.

These three tests take into account all samples simultaneously. The aggregated (AFS) test instead performs all pairwise FS or MFS tests on the samples and aggregates those results by taking the minimum test statistic value and applying a multiple testing procedure.

For clustering, a  $K$ -means algorithm using the generalized version of the Mean Absolute Difference of Distances (MADD) (Sarkar and Ghosh, 2020) is applied. The MADD is defined as

$$\rho_{h,\varphi}(z_i, z_j) = \frac{1}{N-2} \sum_{m \in \{1, \dots, N\} \setminus \{i, j\}} |\varphi_{h,\psi}(z_i, z_m) - \varphi_{h,\psi}(z_j, z_m)|,$$

where  $z_i \in \mathbb{R}^p$ ,  $i = 1, \dots, N$ , denote points from the pooled sample and

$$\varphi_{h,\psi}(z_i, z_j) = h \left( \frac{1}{p} \sum_{l=1}^p \psi |z_{il} - z_{jl}| \right),$$

with  $h : \mathbb{R}^+ \rightarrow \mathbb{R}^+$  and  $\psi : \mathbb{R}^+ \rightarrow \mathbb{R}^+$  continuous and strictly increasing functions. The functions  $h$  and  $\psi$  can be set via changing `s.psi` and `s.h`.

In all cases, high values of the test statistic correspond to similarity between the datasets. Therefore, the null hypothesis of equal distributions is rejected for low values.

The chosen defaults are based on the simulation results of Stolte et al. (2026).

It should be noted that the best choices for `s.psi` and `s.h` differed widely depending on the distribution of the data and the alternative of interest. Refer to the detailed simulation results for more information.

This implementation is a wrapper function around the function `FStest` that modifies the in- and output of that function to match the other functions provided in this package. For more details see `FStest`.

## Value

An object of class `htest` with the following components:

<code>statistic</code>	Observed value of the test statistic
<code>p.value</code>	Asymptotic p value
<code>alternative</code>	The alternative hypothesis
<code>method</code>	Description of the test
<code>data.name</code>	The dataset names
<code>est.cluster.label</code>	The estimated cluster label (not for AFS and MSFS)
<code>observed.cont.table</code>	The observed contingency table of dataset membership and estimated cluster label (not for AFS)
<code>crit.value</code>	The critical value of the test (not for MSFS)
<code>random.gamma</code>	The randomization constant of the test (not for MSFS)
<code>decision</code>	The (overall) test decision
<code>decision.per.k</code>	The test decisions of all individual tests (only for MSFS)
<code>est.cluster.no</code>	The estimated number of clusters (not for MSFS)

**Applicability**

Target variable?	Numeric?	Categorical?	K-sample?
No	Yes	No	Yes

**Note**

In case of `version = "multiscale"` the output is a list object and not of class `htest` as there are multiple test statistic values and corresponding p values.

Note that the aggregated test cannot handle univariate data.

Because this method cannot handle missing data, any missing values are removed automatically and a warning is issued.

GGRL	<i>Decision-Tree Based Measure of Dataset Distance and Two-Sample Test</i>
------	--

---

### Description

Calculates Decision-Tree Based Measure of Dataset Distance by *Ganti et al. (2002)*.

### Usage

```

GGRL(X1, X2, target1 = "y", target2 = "y", n.perm = 0, m = 1, diff.fun = f.a,
      agg.fun = sum, tune = FALSE, k = 5, n.eval = 100, seed = NULL, ...)
GGRLCat(X1, X2, target1 = "y", target2 = "y", n.perm = 0, m = 1, diff.fun = f.aCat,
         agg.fun = sum, tune = FALSE, k = 5, n.eval = 100, seed = NULL, ...)
f.a(sec.parti, X1, X2)
f.s(sec.parti, X1, X2)
f.aCat(sec.parti, X1, X2)
f.sCat(sec.parti, X1, X2)

```

### Arguments

X1	First dataset as matrix or data.frame
X2	Second dataset as matrix or data.frame
target1	Character specifying the column name of the class variable in the first dataset (default: "y")
target2	Character specifying the column name of the class variable in the second dataset (default: "y")
n.perm	Number of permutations for permutation test (default: 0, no permutation test performed)
m	subsampling rate for Bootstrap test (default: 1). <i>Ganti et al. (2002)</i> suggest that 0.2-0.3 is sufficient in many cases. Ignored if n.perm <= 0.
diff.fun	Difference function as function (default: f.a, absolute difference). Other options: f.s (scaled difference), user specified function that takes greatest common refinement (GCR) partition and both datasets as input and returns vector of difference values for each section in the partition.

<code>agg.fun</code>	Aggregate function (default: <code>sum</code> ). Other options are <code>max</code> , or user specified function that takes output of <code>diff.fun</code> and aggregates it into a single value. Note that only for <code>sum</code> it has been shown that the GCR is optimal.
<code>tune</code>	Should the decision tree parameters be tuned? (default: <code>FALSE</code> )
<code>k</code>	Number of folds used in cross-validation for parameter tuning (default: 5). Ignored if <code>tune = FALSE</code> .
<code>n.eval</code>	Number of evaluations for random search used for parameter tuning (default: 100). Ignored if <code>tune = FALSE</code> .
<code>seed</code>	Random seed (default: <code>NULL</code> ). A random seed will only be set if one is provided.
<code>...</code>	Further arguments passed to <code>rpart</code> . Ignored if <code>tune = TRUE</code> .
<code>sec.parti</code>	Intersected partition as output by <code>calculateGCR</code> , i.e. a list containing the intersected partition and each partition on its own as dataframes with limits for each variable.

## Details

The method first calculates the greatest common refinement (GCR), that is the intersection of the sample space partitions induced by a decision tree fit to the first dataset and a decision tree fit to the second dataset. The proportions of samples falling into each section of the GCR is calculated for each dataset. These proportions are compared using a difference function and the results of this are aggregated by the aggregate function.

The implementation uses `rpart` for fitting classification trees to each dataset.

`best.rpart` is used for hyperparameter tuning if `tune = TRUE`. The parameters are tuned using cross-validation and random search. The parameter `minsplits` is tuned over  $2^{(1:7)}$ , `minbucket` is tuned over  $2^{(0:6)}$  and `cp` is tuned over  $10^{\text{seq}(-4, -1, \text{by} = 0.001)}$ .

Pre-implemented methods for the difference function are

$$f_a(\kappa_1, \kappa_2, n_1, n_2) = \left| \frac{\kappa_1}{n_1} - \frac{\kappa_2}{n_2} \right|,$$

and

$$f_s(\kappa_1, \kappa_2, n_1, n_2) = \frac{\left| \frac{\kappa_1}{n_1} - \frac{\kappa_2}{n_2} \right|}{\left( \frac{\kappa_1}{n_1} + \frac{\kappa_2}{n_2} \right) / 2}, \text{ if } \kappa_1 + \kappa_2 > 0,$$

$$= 0 \text{ otherwise,}$$

where  $\kappa_i$  is the number of observations from dataset  $i$  in the respective region of the greatest common refinement and  $n_i$  are the sample sizes,  $i = 1, 2$ .

The aggregate function aggregates the results of the difference function over all regions in the greatest common refinement.

The chosen defaults are based on the simulation results of *Stolte et al. (2026)*.

## Value

An object of class `htest` with the following components:

`statistic`      Observed value of the test statistic

p.value	Permutation p value
alternative	The alternative hypothesis
method	Description of the test
data.name	The dataset names

### Applicability

Target variable?	Numeric?	Categorical?	K-sample?
Yes	Yes	Yes	No

### Note

The categorical method might not work properly if certain combinations of the categorical variables are not present in both datasets. This might happen e.g. for a large number of categories or variables and for small numbers of observations. In this case it might happen that the decision tree of the dataset where the combination is missing is unable to match a level of the split variable to one of the child nodes. Therefore, this combination is not part of the partition of the sample space induced by the tree and therefore also not of the greatest common refinement. Thus, some points of the other dataset cannot be sorted into any region of the greatest common refinement and the probabilities in the joint distribution calculated over the greatest common refinement do not sum up to one anymore. A warning is printed in these cases. It is unclear how this affects the performance.

Note that for small numbers of categories and deep trees it might also happen that the greatest common refinement reduces to all observed combinations of categories in the variables. Then the dataset distance measures is just a complicated way to measure the difference in frequencies of all observed combinations.

Because this method cannot handle missing data, any missing values are removed automatically and a warning is issued.

GPK

*Generalized Permutation-Based Kernel (GPK) Two-Sample Test*

---

## Description

Performs the generalized permutation-based kernel two-sample test proposed by *Song and Chen (2021)*. The implementation here uses the [kerTests](#) implementation from the **kerTests** package.

## Usage

```

GPK(X1, X2, n.perm = 0, fast = (n.perm == 0), M = FALSE,
    sigma = findSigma(X1, X2), r1 = 1.2, r2 = 0.8, seed = NULL)
findSigma(X1, X2)

```

## Arguments

X1	First dataset as matrix or data.frame
X2	Second dataset as matrix or data.frame

n.perm	Number of permutations for permutation test (default: 0, fast test is performed). For fast = FALSE, only the permutation test and no asymptotic test is available. For fast = TRUE, either an asymptotic test (set n.perm = 0) and a permutation test (set n.perm > 0) can be performed.
fast	Should the fast test be performed? (default: TRUE if n.perm = 0, FALSE if n.perm > 0)
M	Should the MMD approximation test be performed? (default: FALSE). Ignored if fast = FALSE.
sigma	Bandwidth parameter of the kernel. By default the median heuristic is used to choose sigma.
r1	Constant in the test statistic $Z_{W,r1}$ for the fast test (default: 1.2, proposed in original article)
r2	Constant in the test statistic $Z_{W,r2}$ for the fast test (default: 0.8, proposed in original article)
seed	Random seed (default: NULL). A random seed will only be set if one is provided.

### Details

The GPK test is motivated by the observation that the MMD test performs poorly for detecting differences in variances. The unbiased MMD<sup>2</sup> estimator for a given kernel function  $k$  can be written as

$$\begin{aligned} \text{MMD}_u^2 &= \alpha + \beta - 2\gamma, \text{ where} \\ \alpha &= \frac{1}{n_1^2 - n_1} \sum_{i=1}^{n_1} \sum_{j=1, j \neq i}^{n_1} k(X_{1i}, X_{1j}), \\ \beta &= \frac{1}{n_2^2 - n_2} \sum_{i=1}^{n_2} \sum_{j=1, j \neq i}^{n_2} k(X_{2i}, X_{2j}), \\ \gamma &= \frac{1}{n_1 n_2} \sum_{i=1}^{n_1} \sum_{j=1}^{n_2} k(X_{1i}, X_{2j}). \end{aligned}$$

The GPK test statistic is defined as

$$\begin{aligned} \text{GPK} &= (\alpha - \text{E}(\alpha), \beta - \text{E}(\beta)) \Sigma^{-1} \begin{pmatrix} \alpha - \text{E}(\alpha) \\ \beta - \text{E}(\beta) \end{pmatrix} \\ &= Z_{W,1}^2 + Z_D^2 \text{ with} \\ Z_{W,r} &= \frac{W_r - \text{E}(W_r)}{\sqrt{\text{Var}(W_r)}}, W_r = r \frac{n_1 \alpha}{n_1 + n_2}, \\ Z_D &= \frac{D - \text{E}(D)}{\sqrt{\text{Var}(D)}}, D = n_1(n_1 - 1)\alpha - n_2(n_2 - 1)\beta, \end{aligned}$$

where the expectations are calculated under the null and  $\Sigma$  is the covariance matrix of  $\alpha$  and  $\beta$  under the null.

The asymptotic null distribution for GPK is unknown. Therefore, only a permutation test can be performed.

For  $r \neq 1$ , the asymptotic null distribution of  $Z_{W,r}$  is normal, but for  $r$  further away from 1, the test performance decreases. Therefore,  $r_1 = 1.2$  and  $r_2 = 0.8$  are proposed as a compromise.

For the fast GPK test, three (asymptotic or permutation) tests based on  $Z_{W,r_1}$ ,  $Z_{W,r_2}$  and  $Z_D$  are conducted and the overall p value is calculated as 3 times the minimum of the three p values.

For the fast MMD test, only the two asymptotic tests based on  $Z_{W,r_1}$ ,  $Z_{W,r_2}$  are used and the p value is 2 times the minimum of the two p values. This is an approximation of the MMD-permutation test, see [MMD](#).

This implementation is a wrapper function around the function [kertestests](#) that modifies the in- and output of that function to match the other functions provided in this package. For more details see the [kertestests](#).

`findSigma` finds the optimal bandwidth parameter of the kernel function using the median heuristic and is a wrapper around [med\\_sigma](#).

### Value

An object of class `htest` with the following components:

<code>statistic</code>	Observed value of the test statistic
<code>p.value</code>	Asymptotic or permutation p value
<code>null.value</code>	Needed for pretty printing of results
<code>alternative</code>	Needed for pretty printing of results
<code>method</code>	Description of the test
<code>data.name</code>	Needed for pretty printing of results

### Applicability

Target variable?	Numeric?	Categorical?	K-sample?
No	Yes	No	No

### Note

Because this method cannot handle missing data, any missing values are removed automatically and a warning is issued.

---

gTests

*Graph-Based Tests*

---

## Description

Performs the edge-count two-sample tests for multivariate data implemented in [g.tests](#) from the **gTests** package. This function is intended to be used e.g. in comparison studies where all four graph-based tests need to be calculated at the same time. Since large parts of the calculation coincide, using this function should be faster than computing all four statistics individually.

## Usage

```
gTests(X1, X2, dist.fun = stats::dist, graph.fun = MST5,
       n.perm = 0, dist.args = NULL, graph.args = NULL,
       maxtype.kappa = 1, seed = NULL)
```

**Arguments**

X1	First dataset as matrix or data.frame
X2	Second dataset as matrix or data.frame
dist.fun	Function for calculating a distance matrix on the pooled dataset (default: <code>stats::dist</code> , Euclidean distance).
graph.fun	Function for calculating a similarity graph using the distance matrix on the pooled sample (default: <code>MST5</code> , 5-Minimum Spanning Tree).
n.perm	Number of permutations for permutation test (default: 0, asymptotic test is performed).
dist.args	Named list of further arguments passed to <code>dist.fun</code> .
graph.args	Named list of further arguments passed to <code>graph.fun</code> .
maxtype.kappa	Parameter $\kappa$ of the maxtype test (default: 1). See <a href="#">ZC</a> .
seed	Random seed (default: NULL). A random seed will only be set if one is provided.

**Details**

The original, weighted, generalized and maxtype edge-count test are performed.

For  $n.perm = 0$ , an asymptotic test using the asymptotic normal approximation of the null distribution is performed. For  $n.perm > 0$ , a permutation test is performed.

This implementation is a wrapper function around the function `g.tests` that modifies the in- and output of that function to match the other functions provided in this package. For more details see the `g.tests`.

**Value**

A list with the following components:

statistic	Observed values of the test statistics
p.value	Asymptotic or permutation p values
alternative	The alternative hypothesis
method	Description of the test
data.name	The dataset names

**Applicability**

Target variable?	Numeric?	Categorical?	K-sample?
No	Yes	No	No

## Note

Because this method cannot handle missing data, any missing values are removed automatically and a warning is issued.

```

gTestsMulti

*Graph-Based Multi-Sample Test***Description**

Performs both proposed graph-based multi-sample test for high-dimensional data by *Song and Chen (2022)*. The implementation here uses the `gtestsmulti` implementation from the **gTestsMulti** package. This function is intended to be used e.g. in comparison studies where both tests need to be calculated at the same time. Since large parts of the calculation coincide, using this function should be faster than computing all four statistics individually.

**Usage**

```
gTestsMulti(X1, X2, ..., n.perm = 0, dist.fun = stats::dist, graph.fun = MST,
            dist.args = NULL, graph.args = NULL, seed = NULL)
```

**Arguments**

X1	First dataset as matrix or data.frame
X2	Second dataset as matrix or data.frame
...	Optionally more datasets as matrices or data.frames
n.perm	Number of permutations for permutation test (default: 0, no permutation test performed)
dist.fun	Function for calculating a distance matrix on the pooled dataset (default: <code>stats::dist</code> , Euclidean distance).
graph.fun	Function for calculating a similarity graph using the distance matrix on the pooled sample (default: <code>MST</code> , Minimum Spanning Tree).
dist.args	Named list of further arguments passed to <code>dist.fun</code> (default: <code>NULL</code> ).
graph.args	Named list of further arguments passed to <code>graph.fun</code> (default: <code>NULL</code> ).
seed	Random seed (default: <code>NULL</code> ). A random seed will only be set if one is provided.

**Details**

Two multi-sample test statistics are defined by Song and Chen (2022) based on a similarity graph. The first one is defined as

$$S = S_W + S_B, \text{ where}$$

$$S_W = (R_W - E(R_W))^T \Sigma_W^{-1} R_W - E(R_W),$$

$$S_B = (R_B - E(R_B))^T \Sigma_W^{-1} R_B - E(R_B),$$

with  $R_W$  denoting the vector of within-sample edge counts and  $R_B$  the vector of between-sample edge counts. Expectations and covariance matrix are calculated under the null.

The second statistic is defined as

$$S_A = (R_A - E(R_A))^T \Sigma_W^{-1} R_A - E(R_A),$$

where  $R_A$  is the vector of all linearly independent edge counts, i.e. the edge counts for all pairs of samples except the last pair  $k - 1$  and  $k$ .

This implementation is a wrapper function around the function `gtestsmulti` that modifies the in- and output of that function to match the other functions provided in this package. For more details see the `gtestsmulti`.

### Value

An list with the following components:

<code>statistic</code>	Observed value of the test statistic
<code>p.value</code>	Bootstrap/ permutation p value (only if <code>n.perm &gt; 0</code> )
<code>estimate</code>	Estimated KMD value
<code>alternative</code>	The alternative hypothesis
<code>method</code>	Description of the test
<code>data.name</code>	The dataset names

### Applicability

Target variable?	Numeric?	Categorical?	K-sample?
No	Yes	No	Yes

### Note

Because this method cannot handle missing data, any missing values are removed automatically and a warning is issued.

```

---

gTests\_cat

*Graph-Based Tests for Discrete Data*

---

## Description

Performs the edge-count two-sample tests for multivariate categorical data implemented in [g.tests](#) from the **gTests** package. This function is intended to be used e.g. in comparison studies where all four graph-based tests need to be calculated at the same time. Since large parts of the calculation coincide, using this function should be faster than computing all four statistics individually.

## Usage

```
gTests_cat(X1, X2, dist.fun = hammingDist, graph.type = "mstree",
           agg.type = "u", K = 5, n.perm = 0, maxtype.kappa = 1.14, seed = NULL)
```

## Arguments

X1	First dataset as matrix or data.frame
X2	Second dataset as matrix or data.frame
dist.fun	Function for calculating the distance of the unique observations. Should take a dataset of the same format as X1 or X2 as its input and return a distance matrix of the pairwise distances in that dataset. Should be appropriate for handling the scale level of the variables present in X1 and X2, e.g. <a href="#">hammingDist</a> for nominal variables, appropriate distances for ordinal data or the Gower distance for mixed nominal and ordinal data.
agg.type	Character giving the method for aggregating over possible similarity graphs. Options are "u" for union of possible similarity graphs (default) and "a" for averaging over test statistics calculated on possible similarity graphs.
graph.type	Character specifying which similarity graph to use. Possible options are "mstree" (default, Minimum Spanning Tree) and "nnlink" (Nearest Neighbor Graph).
K	Parameter for graph (default: 5). If graph.type = "mstree", a K-MST is constructed (K=1 is the classical MST). If graph.type = "nnlink", K gives the number of neighbors considered in the K-NN graph.
n.perm	Number of permutations for permutation test (default: 0, asymptotic test is performed).

maxtype.kappa	Parameter $\kappa$ of the maxtype test (default: 1.14). See <a href="#">ZC</a> .
seed	Random seed (default: NULL). A random seed will only be set if one is provided.

## Details

The original, weighted, generalized and maxtype edge-count test are performed.

For discrete data, the similarity graph used in the test is not necessarily unique. This can be solved by either taking a union ("u") of all optimal similarity graphs or averaging ("a") the test statistics over all optimal similarity graphs. For details, see *Zhang and Chen (2022)*. Both options are performed here.

For  $n.perm = 0$ , an asymptotic test using the asymptotic normal approximation of the null distribution is performed. For  $n.perm > 0$ , a permutation test is performed.

The chosen defaults are based on the simulation results of *Stolte et al. (2025)*.

This implementation is a wrapper function around the function [g.tests](#) that modifies the in- and output of that function to match the other functions provided in this package. For more details see the [g.tests](#).

## Value

A list with the following components:

statistic	Observed values of the test statistics
p.value	Asymptotic or permutation p values
alternative	The alternative hypothesis
method	Description of the test
data.name	The dataset names

## Applicability

Target variable?	Numeric?	Categorical?	K-sample?
No	No	Yes	No

## Note

Because this method cannot handle missing data, any missing values are removed automatically and a warning is issued.

HamiltonPath

*Shortest Hamilton path*

---

## Description

The function implements a heuristic approach to determine the shortest Hamilton path of a graph based on Kruskal's algorithm.

**Usage**

```
HamiltonPath(X1, X2, seed = NULL)
```

**Arguments**

X1	First dataset as matrix
X2	Second dataset as matrix
seed	Random seed (default: NULL). A random seed will only be set if one is provided.

**Details**

Uses function [IsAcyclic](#) from package **rlemon** to check if the addition of an edge leads to a cyclic graph.

**Value**

Returns an edge list containing only the edges needed to construct the Hamilton path

**See Also**

[BMG](#)

**Examples**

```
# create data for two datasets
data <- data.frame(x = c(1.5, 2, 4, 5, 4, 6, 5.5, 8),
                  y = c(6, 4, 5.5, 3, 3.5, 5.5, 7, 6),
                  dataset = rep(c(1, 2), each = 4))

plot(data$x, data$y, pch = c(21, 19)[data$dataset])

# divide into the two datasets and calculate Hamilton path
X1 <- data[1:4, ]
X2 <- data[5:8, ]

if(requireNamespace("rlemon", quietly = TRUE)) {
  E <- HamiltonPath(X1, X2)

  # plot the resulting edges
  segments(x0 = data$x[E[, 1]], y0 = data$y[E[, 1]],
          x1 = data$x[E[, 2]], y1 = data$y[E[, 2]],
          lwd = 2)
}
```

HMN

*Random Forest Based Two-Sample Test***Description**

Performs the random forest based two-sample test proposed by *Hediger et al. (2022)*. The implementation here uses the [hypoRF](#) implementation from the **hypoRF** package.

**Usage**

```
HMN(X1, X2, n.perm = 0, statistic = "PerClassOOB", normal.approx = FALSE,
     seed = NULL, ...)
```

**Arguments**

X1	First dataset as matrix or data.frame
X2	Second dataset as matrix or data.frame
n.perm	Number of permutations for permutation test (default: 0, binomial test is performed).
statistic	Character specifying the test statistic. Possible options are "PerClassOOB" (default) corresponding to the sum of out-of-bag (OOB) per class errors, and "OverallOOB" corresponding to the overall OOB error.
normal.approx	Should a normal approximation be used in the permutation test procedure? (default: FALSE)
seed	Random seed (default: NULL). A random seed will only be set if one is provided.
...	Arguments passed to <a href="#">ranger</a>

**Details**

For the test, a random forest is fitted to the pooled dataset where the target variable is the original dataset membership. The test statistic is either the overall out-of-bag classification accuracy or the sum or mean of the per-class out-of-bag errors for the permutation test. For the asymptotic test ( $n.perm = 0$ ), the pooled dataset is split into a training and test set and the test statistic is either the overall classification error on the test set or the mean of the per-class classification errors on the test set. In the former case, a binomial test is performed, in the latter case, a Wald test is performed. If the underlying distributions coincide, classification errors close to chance level are expected. The test rejects for small classification errors.

Note that the per class OOB statistic differs for the permutation test and approximate test: for the permutation test, the sum of the per class OOB errors is returned, for the asymptotic version, the standardized sum is returned.

Note that empirically the test performed bad for unbalanced sample sizes (*Stolte et al., 2026*).

This implementation is a wrapper function around the function [hypoRF](#) that modifies the in- and output of that function to match the other functions provided in this package. For more details see [hypoRF](#).

**Value**

An object of class `htest` with the following components:

<code>statistic</code>	Observed value of the test statistic
<code>parameter</code>	Parameter(s) of the null distribution
<code>p.value</code>	Asymptotic p value
<code>alternative</code>	The alternative hypothesis
<code>method</code>	Description of the test
<code>data.name</code>	The dataset names
<code>val</code>	The OOB statistic values for the permuted data (for <code>n.perm &gt; 0</code> )
<code>varest</code>	The estimated variance of the OOB statistic values for the permuted data (for <code>n.perm &gt; 0</code> )
<code>importance_ranking</code>	Variable importance (for <code>importance = "impurity"</code> )
<code>cutoff</code>	The quantile of the importance distribution at level $\alpha$

**Applicability**

Target variable?	Numeric?	Categorical?	K-sample?
No	Yes	Yes	No

**Note**

Because this method cannot handle missing data, any missing values are removed automatically and a warning is issued.

}

```

---

Jeffreys

*Jeffreys Divergence*

---

## Description

The function implements Jeffreys divergence by using KL Divergence Approximation (*Sugiyama et al. 2013*). By default, the implementation uses method KLIEP of function `densratio` from the `densratio` package for density ratio estimation.

## Usage

```
Jeffreys(X1, X2, fitting.method = "KLIEP", verbose = FALSE, seed = NULL)
```

## Arguments

X1	First dataset as matrix or data.frame
X2	Second dataset as matrix or data.frame
fitting.method	"KLIEP" (default), "uLSIF" or "RuLSIF"
verbose	logical (default: FALSE)
seed	Random seed (default: NULL). A random seed will only be set if one is provided.

## Details

Jeffreys divergence is calculated as the sum of the two KL-divergences

$$\text{KL}(F_1, F_2) = \int \log \left( \frac{f_1}{f_2} \right) dF_1$$

where each dataset is used as the first dataset once. As suggested by *Sugiyama et al. (2013)* the method KLIEP is used for density ratio estimation by default. In the simulations of *Stolte et al. (2026)*, KLIEP was numerically less stable than the other options but often outperformed the other options if it converged. Low values of Jeffreys Divergence indicate similarity.

**Value**

An object of class `htest` with the following components:

<code>statistic</code>	Observed value of the test statistic
<code>p.value</code>	p value
<code>method</code>	Description of the test
<code>data.name</code>	The dataset names
<code>alternative</code>	The alternative hypothesis

**Applicability**

Target variable?	Numeric?	Categorical?	K-sample?
No	Yes	No	No

**Note**

Because this method cannot handle missing data, any missing values are removed automatically and a warning is issued.

kerTests

*Generalized Permutation-Based Kernel (GPK) Two-Sample Test***Description**

Performs the generalized permutation-based kernel two-sample tests proposed by *Song and Chen (2021)*. The implementation here uses the `kertests` implementation from the `kerTests` package. This function is intended to be used e.g. in comparison studies where all four test statistics need to be calculated at the same time. Since large parts of the calculation coincide, using this function should be faster than computing all four statistics individually.

**Usage**

```
kerTests(X1, X2, n.perm = 0, sigma = findSigma(X1, X2), r1 = 1.2,
        r2 = 0.8, seed = NULL)
```

**Arguments**

X1	First dataset as matrix or data.frame
X2	Second dataset as matrix or data.frame
n.perm	Number of permutations for permutation test (default: 0, fast test is performed). For fast = FALSE, only the permutation test and no asymptotic test is available. For fast = TRUE, either an asymptotic test (set n.perm = 0) and a permutation test (set n.perm > 0) can be performed.
sigma	Bandwidth parameter of the kernel. By default the median heuristic is used to choose sigma.
r1	Constant in the test statistic $Z_{W,r1}$ for the fast test (default: 1.2, proposed in original article)
r2	Constant in the test statistic $Z_{W,r2}$ for the fast test (default: 0.8, proposed in original article)
seed	Random seed (default: NULL). A random seed will only be set if one is provided.

**Details**

The GPK test is motivated by the observation that the MMD test performs poorly for detecting differences in variances. The unbiased  $\text{MMD}^2$  estimator for a given kernel function  $k$  can be written as

$$\text{MMD}_u^2 = \alpha + \beta - 2\gamma, \text{ where}$$

$$\alpha = \frac{1}{n_1^2 - n_1} \sum_{i=1}^{n_1} \sum_{j=1, j \neq i}^{n_1} k(X_{1i}, X_{1j}),$$

$$\beta = \frac{1}{n_2^2 - n_2} \sum_{i=1}^{n_2} \sum_{j=1, j \neq i}^{n_2} k(X_{2i}, X_{2j}),$$

$$\gamma = \frac{1}{n_1 n_2} \sum_{i=1}^{n_1} \sum_{j=1}^{n_2} k(X_{1i}, X_{2j}).$$

The GPK test statistic is defined as

$$\begin{aligned} \text{GPK} &= (\alpha - \mathbf{E}(\alpha), \beta - \mathbf{E}(\beta)) \Sigma^{-1} \begin{pmatrix} \alpha - \mathbf{E}(\alpha) \\ \beta - \mathbf{E}(\beta) \end{pmatrix} \\ &= Z_{W,1}^2 + Z_D^2 \text{ with} \\ Z_{W,r} &= \frac{W_r - \mathbf{E}(W_r)}{\sqrt{\text{Var}(W_r)}}, W_r = r \frac{n_1 \alpha}{n_1 + n_2}, \\ Z_D &= \frac{D - \mathbf{E}(D)}{\sqrt{\text{Var}(D)}}, D = n_1(n_1 - 1)\alpha - n_2(n_2 - 1)\beta, \end{aligned}$$

where the expectations are calculated under the null and  $\Sigma$  is the covariance matrix of  $\alpha$  and  $\beta$  under the null.

The asymptotic null distribution for GPK is unknown. Therefore, only a permutation test can be performed.

For  $r \neq 1$ , the asymptotic null distribution of  $Z_{W,r}$  is normal, but for  $r$  further away from 1, the test performance decreases. Therefore,  $r_1 = 1.2$  and  $r_2 = 0.8$  are proposed as a compromise.

For the fast GPK test, three (asymptotic or permutation) tests based on  $Z_{W,r_1}$ ,  $Z_{W,r_2}$  and  $Z_D$  are conducted and the overall p value is calculated as 3 times the minimum of the three p values.

For the fast MMD test, only the two asymptotic tests based on  $Z_{W,r_1}$ ,  $Z_{W,r_2}$  are used and the p value is 2 times the minimum of the two p values. This is an approximation of the MMD-permutation test, see [MMD](#).

This implementation is a wrapper function around the function [kerTests](#) that modifies the in- and output of that function to match the other functions provided in this package. For more details see the [kerTests](#).

## Value

A list with the following components:

statistic	Observed values of the test statistics
p.value	Asymptotic or permutation p values
null.value	Needed for pretty printing of results
alternative	Needed for pretty printing of results
method	Description of the test
data.name	Needed for pretty printing of results

**Applicability**

Target variable?	Numeric?	Categorical?	K-sample?
No	Yes	No	No

KMD

*Kernel Measure of Multi-Sample Dissimilarity (KMD)*

---

**Description**

Calculates the kernel measure of multi-sample dissimilarity (KMD) and performs a permutation multi-sample test (*Huang and Sen, 2023*). The implementation here uses the [KMD](#) and [KMD\\_test](#) implementations from the **KMD** package.

**Usage**

```
KMD(X1, X2, ..., n.perm = 0, graph = "knn", k = ceiling(N/10),
    kernel = "discrete", seed = NULL)
```

**Arguments**

X1	First dataset as matrix or data.frame
X2	Second dataset as matrix or data.frame
...	Optionally more datasets as matrices or data.frames
n.perm	Number of permutations for permutation test (default: 0, no permutation test performed).
graph	Graph used in calculation of KMD. Possible options are "knn" (default) and "mst".
k	Number of neighbors for construction of k-nearest neighbor graph. Ignored for graph = "mst".
kernel	Kernel used in calculation of KMD. Can either be "discrete" (default) for use of the discrete kernel or a kernel matrix with numbers of rows and columns corresponding to the number of datasets. For the latter, the entry in the $i$ -th row and $j$ -th column corresponds to the kernel value $k(i, j)$ .
seed	Random seed (default: NULL). A random seed will only be set if one is provided.

**Details**

Given the pooled sample  $Z_1, \dots, Z_N$  and the corresponding sample memberships  $\Delta_1, \dots, \Delta_N$  let  $\mathcal{G}$  be a geometric graph on  $\mathcal{X}$  such that an edge between two points  $Z_i$  and  $Z_j$  in the pooled sample implies that  $Z_i$  and  $Z_j$  are close, e.g.  $K$ -nearest neighbor graph with  $K \geq 1$  or MST. Denote by  $(Z_i, Z_j) \in \mathcal{E}(\mathcal{G})$  that there is an edge in  $\mathcal{G}$  connecting  $Z_i$  and  $Z_j$ . Moreover, let  $o_i$  be the out-degree of  $Z_i$  in  $\mathcal{G}$ . Then an estimator for the KMD  $\eta$  is defined as

$$\hat{\eta} := \frac{\frac{1}{N} \sum_{i=1}^N \frac{1}{o_i} \sum_{j:(Z_i, Z_j) \in \mathcal{E}(\mathcal{G})} K(\Delta_i, \Delta_j) - \frac{1}{N(N-1)} \sum_{i \neq j} K(\Delta_i, \Delta_j)}{\frac{1}{N} \sum_{i=1}^N K(\Delta_i, \Delta_i) - \frac{1}{N(N-1)} \sum_{i \neq j} K(\Delta_i, \Delta_j)}.$$

Euclidean distances are used for computing the KNN graph (ties broken at random) and the MST.

For  $n.perm == 0$ , an asymptotic test using the asymptotic normal approximation of the null distribution is performed. For this, the KMD is standardized by the null mean and standard deviation. For  $n.perm > 0$ , a permutation test is performed, i.e. the observed KMD statistic is compared to the permutation KMD statistics.

The theoretical KMD of two distributions is zero if and only if the distributions coincide. It is upper bound by one. Therefore, low values of the empirical KMD indicate similarity and the test rejects for high values.

*Huang and Sen (2023)* recommend using the  $k$ -NN graph for its flexibility, but the choice of  $k$  is unclear. Based on the simulation results in the original article, the recommended values are  $k = 0.1N$  for testing and  $k = 1$  for estimation. For increasing power it is beneficial to choose large values of  $k$ , for consistency of the tests,  $k = o(N/\log(N))$  together with a continuous distribution of inter-point distances is sufficient, i.e.  $k$  cannot be chosen too large compared to  $N$ . On the other hand, in the context of estimating the KMD, choosing  $k$  is a bias-variance trade-off with small values of  $k$  decreasing the bias and larger values of  $k$  decreasing the variance (for more details see discussion in Appendix D.3 of *Huang and Sen (2023)*). The simulation results of *Stolte et al. (2026)* confirm good performance of the heuristic choice of  $k$  but also show differences in which

of the considered values performs best depending on the distribution of the data and the alternative of interest.

This implementation is a wrapper function around the functions `KMD` and `KMD_test` that modifies the in- and output of those functions to match the other functions provided in this package. For more details see `KMD` and `KMD_test`.

### Value

An object of class `htest` with the following components:

<code>statistic</code>	Observed value of the test statistic
<code>p.value</code>	Permutation / asymptotic p value
<code>estimate</code>	Estimated KMD value
<code>alternative</code>	The alternative hypothesis
<code>method</code>	Description of the test
<code>data.name</code>	The dataset names
<code>graph</code>	Graph used for calculation
<code>k</code>	Number of neighbors used if graph is the KNN graph.
<code>kernel</code>	Kernel used for calculation

### Applicability

Target variable?	Numeric?	Categorical?	K-sample?
No	Yes	No	Yes

### Note

Because this method cannot handle missing data, any missing values are removed automatically and a warning is issued.

---

**knn***K-Nearest Neighbor Graph*

---

**Description**

Calculate the edge matrix of a K-nearest neighbor graph based on a distance matrix, used as helper functions in [SH](#)

**Usage**

```
knn(dists, K = 1)
knn.fast(dists, K = 1)
knn.bf(dists, K = 1)
```

**Arguments**

dists	Distance matrix
K	Number of nearest neighbors to consider (default: K = 1)

**Details**

`knn.bf` uses brute force to find the K nearest neighbors but does not require additional packages. `knn` uses the [kNN](#) implementation of the **dbscan** package. `knn.fast` uses the [get.knn](#) implementation of the **FNN** package that uses a kd-tree for fast K-nearest neighbor search.

**Value**

The edge matrix of the K-nearest neighbor graph. The first column gives the index of the first node of each edge. The second column gives the index of the second node of each edge. Thus, the second entry of each row is one of the K nearest neighbors of the first entry in each row.

**See Also**[SH](#)

**Examples**

```

set.seed(1234)
X1 <- matrix(rnorm(1000), ncol = 10)
X2 <- matrix(rnorm(1000, mean = 0.5), ncol = 10)
dists <- stats::dist(rbind(X1, X2))
# Nearest neighbor graph
if(requireNamespace("dbscan", quietly = TRUE)) {
  knn(dists)
}

if(requireNamespace("FNN", quietly = TRUE)) {
  knn.fast(dists)
}
knn.bf(dists)
# 5-Nearest neighbor graph
if(requireNamespace("dbscan", quietly = TRUE)) {
  knn(dists, K = 5)
}
if(requireNamespace("FNN", quietly = TRUE)) {
  knn.fast(dists, K = 5)
}
knn.bf(dists, K = 5)

```

---

LHZ

*Empirical Characteristic Distance*

---

**Description**

The function implements the *Li et al. (2022)* empirical characteristic distance between two datasets.

**Usage**

```
LHZ(X1, X2, n.perm = 0, seed = NULL)
```

**Arguments**

X1	First dataset as matrix or data.frame
X2	Second dataset as matrix or data.frame
n.perm	Number of permutations for permutation test (default: 0, no permutation test performed)
seed	Random seed (default: NULL). A random seed will only be set if one is provided.

## Details

The test statistic

$$T_{n,m} = \frac{1}{n^2} \sum_{j,q=1}^n \left( \left\| \frac{1}{n} \sum_{k=1}^n e^{i\langle X_k, X_j - X_q \rangle} - \frac{1}{m} \sum_{l=1}^m e^{i\langle Y_l, X_j - X_q \rangle} \right\|^2 \right) + \frac{1}{m^2} \sum_{j,q=1}^m \left( \left\| \frac{1}{n} \sum_{k=1}^n e^{i\langle X_k, Y_j - Y_q \rangle} - \frac{1}{m} \sum_{l=1}^m e^{i\langle Y_l, Y_j - Y_q \rangle} \right\|^2 \right)$$

is calculated according to *Li et al. (2022)*. The datasets are denoted by  $X$  and  $Y$  with respective sample sizes  $n$  and  $m$ . By  $X_j$  the  $i$ -th row of dataset  $X$  is denoted. Furthermore,  $\| \cdot \|$  indicates the Euclidian norm and  $\langle X_i, X_j \rangle$  indicates the inner product between  $X_i$  and  $X_j$ .

Low values of the test statistic indicate similarity. Therefore, the permutation test rejects for large values of the test statistic.

## Value

An object of class `htest` with the following components:

<code>method</code>	Description of the test
<code>statistic</code>	Observed value of the test statistic
<code>p.value</code>	Permutation p value (only if <code>n.perm &gt; 0</code> )
<code>data.name</code>	The dataset names
<code>alternative</code>	The alternative hypothesis

## Applicability

Target variable?	Numeric?	Categorical?	K-sample?
No	Yes	No	No

## Note

Because this method cannot handle missing data, any missing values are removed automatically and a warning is issued.

method.table

*List of Methods Included in the Package***Description**

The dataset contains the subset of methods that are implemented in the **DataSimilarity** package from the results table of *Stolte et al. (2024)*.

**Usage**

```
data("method.table")
```

**Format**

A data frame with 42 observations on the following 30 variables that include information on whether or not the method fulfills the theoretical criteria of *Stolte et al. (2024)*. Some criteria are only fulfilled for certain parameter choices of the method ("Conditionally Fulfilled") or do not apply to the method. NA values mean that there is no information available on whether or not the respective criterion is fulfilled.

`Method` a character vector giving the reference or method name

`Implementation` a character vector giving the function name of the implementation in the **DataSimilarity** package

`Target.Inclusion` a character vector. Can the method handle datasets that include a target variable in a meaningful way?

`Numeric` a character vector. Can the method handle numeric data?

`Categorical` a character vector. Can the method handle categorical data?

`Unequal.Sample.Sizes` a character vector. Can the method handle datasets of different sample sizes?

`p.Larger.N` a character vector. Can the method handle datasets with more variables than observations?

`Multiple.Samples` a character vector. Can the method handle  $k > 2$  datasets simultaneously?

`Without.training` a character vector. Does the method work without holding out training data?

`No.assumptions` a character vector. Does the method work without further assumptions?

`No.parameters` a character vector. Does the method work without the specification or tuning of additional parameters?

`Implemented` a character vector. Is the method implemented elsewhere? (NA if no other implementations are known)

`Complexity` a character vector giving the computational complexity of the method.

`Interpretable.units` a character vector. Can a one unit increase of the output value be interpreted?

`Lower.bound` a character vector. Are the output values lower bounded? If known the lower bound is given.

- Upper.bound a character vector. Are the output values upper bounded? If known the upper bound is given.
- Rotation.invariant a character vector. Is the method invariant to rotation of all datasets?
- Location.change.invariant a character vector. Is the method invariant to shifting all datasets?
- Homogeneous.scale.invariant a character vector. Is the method invariant to scaling all datasets?
- Positive.definite a character vector. Is the method positive definite, i.e.  $d(F_1, F_2) \geq 0$  and  $d(F_1, F_2) = 0 \Leftrightarrow F_1 = F_2$  for any two distributions  $F_1, F_2$ ?
- Symmetric a character vector. Ist the method symmetric, i.e.  $d(F_1, F_2) = d(F_2, F_1)$  for any two distributions  $F_1, F_2$ ?
- Triangle.inequality a character vector. Does the method fulfill the triangle inequality, i.e.  $d(F_1, F_2) \leq d(F_1, F_3) + d(F_3, F_2)$  for any three distributions  $F_1, F_2, F_3$ ?
- Consistency.N a character vector. Is the corresponding test consistent for  $N \rightarrow \infty$ ?
- Consistency.p a character vector. Is the corresponding test consistent for  $p \rightarrow \infty$ ?
- Number.Fulfilled a numeric vector. Number of fulfilled criteria.
- Number.Cond.Fulfilled a numeric vector. Number of conditionally fulfilled criteria.
- Number.Unfulfilled a numeric vector. Number of unfulfilled criteria.
- Number.NA a numeric vector. Number of criteria for which it is unknown if they are fulfilled.
- Class a character vector. Class of the taxonomy of *Stolte et al. (2024)* that the method is assigned to based on its underlying idea.
- Subclass a character vector. Subclass of the taxonomy of *Stolte et al. (2024)* that the method is assigned to based on its underlying idea.

## Details

The dataset is based on the results of *Stolte et al. (2024)*. For explanations on the criteria and on the taxonomy and classes, please refer to that publication. A full version of the table can also be found at <https://shiny.statistik.tu-dortmund.de/data-similarity/>.

```

---

MMCM

*Multisample Mahalanobis Crossmatch (MMCM) Test*

---

**Description**

Performs the multisample Mahalanobis crossmatch (MMCM) test (*Mukherjee et al., 2022*).

**Usage**

```
MMCM(X1, X2, ..., dist.fun = stats::dist, dist.args = NULL, seed = NULL, shuffle = FALSE)
```

**Arguments**

<code>X1</code>	First dataset as matrix or data.frame
<code>X2</code>	Second dataset as matrix or data.frame
<code>...</code>	Optionally more datasets as matrices or data.frames
<code>dist.fun</code>	Function for calculating a distance matrix on the pooled dataset (default: <code>stats::dist</code> , Euclidean distance).
<code>dist.args</code>	Named list of further arguments passed to <code>dist.fun</code> (default: <code>NULL</code> ).
<code>seed</code>	Random seed (default: <code>NULL</code> ). A random seed will only be set if one is provided.
<code>shuffle</code>	Logical indicator specifying whether the pooled sample should be randomly permuted before matching in the presence of ties (default: <code>FALSE</code> ).

**Details**

The test is an extension of the *Rosenbaum (2005)* crossmatch test to multiple samples. Its test statistic is the Mahalanobis distance of the observed cross-counts of all pairs of datasets.

It aims to improve the power for large dimensions or numbers of groups compared to another extension, the multisample crossmatch (MCM) test (*Petrie, 2016*).

The observed cross-counts are calculated using the functions `distancematrix` and `nonbimatch` from the **nbpMatching** package.

Small values of the test statistic indicate similarity of the datasets, therefore the test rejects the null hypothesis of equal distributions for large values of the test statistic.

Note that due to the specific implementation of the non-bipartite matching algorithm, inflated cross-counts in case of high numbers of ties in the distance matrix were observed in simulations under the null scenario, see note below. Therefore, the option to shuffle the dataset before the matching algorithm was introduced to circumvent this inflated cross-counts. A warning is thrown in case any ties in the distance matrix are detected.

**Value**

An object of class `htest` with the following components:

<code>statistic</code>	Observed value of the test statistic
<code>p.value</code>	Asymptotic p value
<code>alternative</code>	The alternative hypothesis
<code>method</code>	Description of the test
<code>data.name</code>	The dataset names

**Applicability**

Target variable?	Numeric?	Categorical?	K-sample?
No	Yes	Yes	Yes

## Note

In case of ties in the distance matrix, the optimal non-bipartite matching might not be defined uniquely. Here, the observations are matched in the order in which the samples are supplied. When searching for a match, the implementation starts at the end of the pooled sample. Therefore, with many ties (e.g. for categorical data), observations from the first dataset are often matched with ones from the last dataset and so on. This might affect the validity of the test negatively. For this reason, a warning is issued whenever ties are detected. As a workaround, users can set `shuffle = TRUE` in the function call, which randomly permutes the pooled sample before matching. When using this option, it is strongly recommended to set a random seed to ensure reproducibility.

Because this method cannot handle missing data, any missing values are removed automatically and a warning is issued.

## Examples

```
set.seed(1234)
# Draw some data
X1 <- matrix(rnorm(1000), ncol = 10)
X2 <- matrix(rnorm(1000, mean = 0.5), ncol = 10)
X3 <- matrix(rnorm(1000, mean = 0.5), ncol = 10)
# Perform MMCM test
if(requireNamespace("nbpMatching", quietly = TRUE)) {
  MMCM(X1, X2, X3)
}
```

MMD

*Maximum Mean Discrepancy (MMD) Test***Description**

Performs a two-sample test based on the maximum mean discrepancy (MMD) using either, the Rademacher or the asymptotic bounds or a permutation testing procedure. The implementation adds a permutation test to the `kmmd` implementation from the **kernelab** package.

**Usage**

```
MMD(X1, X2, n.perm = 0, alpha = 0.05, asymptotic = FALSE, replace = TRUE,
     n.times = 150, frac = 1, seed = NULL, ...)
```

**Arguments**

<code>X1</code>	First dataset as matrix or data.frame
<code>X2</code>	Second dataset as matrix or data.frame
<code>n.perm</code>	Number of permutations for permutation test (default: 0, asymptotic test is performed).
<code>alpha</code>	Significance level of the test (default: 0.05). Used to calculate asymptotic or Rademacher bound.
<code>asymptotic</code>	Should the asymptotic bound be calculated? (default: FALSE, Rademacher bound is used, TRUE calculation of asymptotic bounds is suitable for smaller datasets)
<code>replace</code>	Should sampling with replacement be used in computation of asymptotic bounds? (default: TRUE)
<code>n.times</code>	Number of repetitions for sampling procedure (default: 150)
<code>frac</code>	Fraction of points to sample (default: 1)
<code>seed</code>	Random seed (default: NULL). A random seed will only be set if one is provided.
<code>...</code>	Further arguments passed to <code>kmmd</code> specifying the kernel. E.g. <code>kernel</code> for passing the kernel as a character (default: <code>rbfdot</code> RBF kernel function) and <code>kpar</code> for passing the kernel parameter(s) as a named list (default: "automatic" uses heuristic for choosing a good bandwidth for the RBF or Laplace kernel). For details, see <code>kmmd</code> .

**Details**

For a given kernel function  $k$  an unbiased estimator for  $\text{MMD}^2$  is defined as

$$\widehat{\text{MMD}}^2(\mathcal{H}, X_1, X_2)_U = \frac{1}{n_1(n_1 - 1)} \sum_{i=1}^{n_1} \sum_{\substack{j=1 \\ j \neq i}}^{n_1} k(X_{1i}, X_{1j}) + \frac{1}{n_2(n_2 - 1)} \sum_{i=1}^{n_2} \sum_{\substack{j=1 \\ j \neq i}}^{n_2} k(X_{2i}, X_{2j}) - \frac{2}{n_1 n_2} \sum_{i=1}^{n_1} \sum_{\substack{j=1 \\ j \neq i}}^{n_2} k(X_{1i}, X_{2j})$$

Its square root is returned as the statistic here.

The theoretical MMD of two distributions is equal to zero if and only if the two distributions coincide. Therefore, low values indicate similarity of datasets and the test rejects for large values.

The original proposal of the test is based on critical values calculated asymptotically or using Rademacher bounds. Here, the option for calculating a permutation p value is added. The Rademacher bound is always returned. Additionally, the asymptotic bound can be returned depending on the value of `asymptotic`.

This implementation is a wrapper function around the function `kmmd` that modifies the in- and output of that function to match the other functions provided in this package. Moreover, a permutation test is added. For more details see the `kmmd`.

### Value

An object of class `htest` with the following components:

<code>statistic</code>	Observed value of the test statistic
<code>p.value</code>	Permutation p value
<code>method</code>	Description of the test
<code>data.name</code>	The dataset names
<code>alternative</code>	The alternative hypothesis
<code>H0</code>	Is $H_0$ rejected according to the Rademacher bound?
<code>asympt.H0</code>	Is $H_0$ rejected according to the asymptotic bound?
<code>kernel.fun</code>	Kernel function used
<code>Rademacher.bound</code>	The Rademacher bound
<code>asympt.bound</code>	The asymptotic bound

### Applicability

Target variable?	Numeric?	Categorical?	K-sample?
No	Yes	When suitable kernel function is passed	No

### Note

Because this method cannot handle missing data, any missing values are removed automatically and a warning is issued.

MST

*Minimum Spanning Tree (MST)*

---

## Description

Calculate the edge matrix of a minimum spanning tree based on a distance matrix, used as helper functions in [CCS](#), [CF](#), [FR](#), and [ZC](#). This function is a wrapper around [mstree](#). MST5 is a convenience wrapper for the 5-MST.

## Usage

```
MST(dists, K = 1)
MST5(dists)
```

## Arguments

dists	Distance matrix as dist object.
K	Component number (default: K = 1).

## Details

For more details see [mstree](#).

## Value

Object of class neig.

## See Also

## Examples

```

set.seed(1234)
X1 <- matrix(rnorm(20), ncol = 2)
X2 <- matrix(rnorm(20, mean = 0.5), ncol = 2)
dists <- stats::dist(rbind(X1, X2))
if(requireNamespace("ade4", quietly = TRUE)) {
  # MST
  MST(dists)
  # 5-MST
  MST5(dists)
}

```

---

 MW

*Nonparametric Graph-Based LP (GLP) Test*

---

## Description

Performs the nonparametric graph-based LP (GLP) multisample test proposed by *Mokhopadhyay and Wang (2020)*. The implementation here uses the [GLP](#) implementation from the **LPKsample** package.

## Usage

```

MW(X1, X2, ..., sum.all = FALSE, m.max = 4, components = NULL, alpha = 0.05,
  c.poly = 0.5, clust.alg = "kmeans", n.perm = 0, combine.criterion = "kernel",
  multiple.comparison = TRUE, compress.algorithm = FALSE, nbasis = 8, seed = NULL)

```

## Arguments

X1	First dataset as matrix or data.frame
X2	Second dataset as matrix or data.frame
...	Optionally more datasets as matrices or data.frames
sum.all	Should all components be summed up for calculating the test statistic? (default: FALSE, only significant components are summed up)
m.max	Maximum order of LP components to investigate (default: 4)
components	Vector specifying which components to test. If components is not NULL (default), only the specified components are examined and m.max is ignored.
alpha	Significance level $\alpha$ (default: 0.05)
c.poly	Parameter for polynomial kernel (default: 0.5)
clust.alg	Character specifying the cluster algorithm used in graph community detection. possible options are "kmeans" (default) and "mclust".
n.perm	Number of permutations for permutation test (default: 0, asymptotic test is performed).

<code>combine.criterion</code>	Character specifying how to obtain the overall test result based on the component-wise results. Possible options are "kernel" meaning that an overall kernel $W$ is computed based on the significant components and the LP graph test is run on $W$ , and "pvalue" which uses Fisher's method to combine the p values from each component.
<code>multiple.comparison</code>	Should an adjustment for multiple comparisons be used when determining which components are significant? (default: TRUE)
<code>compress.algorithm</code>	Should smooth compression of Laplacian spectra be used for testing? (default: FALSE). It is recommended to set this to TRUE for large sample sizes.
<code>nbasis</code>	Number of bases used for approximation when <code>compress.algorithm = TRUE</code> (default: 8)
<code>seed</code>	Random seed (default: NULL). A random seed will only be set if one is provided.

### Details

The GLP statistic is based on learning an LP graph kernel using a pre-specified number of LP components and performing clustering on the eigenvectors of the Laplacian matrix for this learned kernel. The cluster assignment is tested for association with the true dataset memberships for each component of the LP graph kernel. The results are combined by either constructing a super-kernel using specific components and performing the cluster and test step again or by using the combination of the significant components after adjustment for multiple testing.

Small values of the GLP statistic indicate dataset similarity. Therefore, the test rejects for large values.

### Value

An object of class `htest` with the following components:

<code>statistic</code>	Observed value of the GLP test statistic
<code>p.value</code>	Asymptotic or permutation overall p value
<code>null.value</code>	Needed for pretty printing of results
<code>alternative</code>	Needed for pretty printing of results
<code>method</code>	Description of the test
<code>data.name</code>	The dataset names
<code>alternative</code>	The alternative hypothesis

### Applicability

Target variable?	Numeric?	Categorical?	K-sample?
No	Yes	No	Yes

**Note**

When `sum.all = FALSE` and no components are significant, the test statistic value is always set to zero.

Note that the implementation cannot handle univariate data.

Because this method cannot handle missing data, any missing values are removed automatically and a warning is issued.

}
```

---

NKT

*Decision-Tree Based Measure of Dataset Similarity (Ntoutsis et al., 2008)*

---

**Description**

Calculates Decision-Tree Based Measure of Dataset Similarity by Ntoutsis et al. (2008).

**Usage**

```
NKT(X1, X2, target1 = "y", target2 = "y", version = 1, tune = FALSE, k = 5,
    n.eval = 100, seed = NULL, ...)
```

**Arguments**

X1	First dataset as matrix or data.frame
X2	Second dataset as matrix or data.frame
target1	Character specifying the column name of the class variable in the first dataset (default: "y")
target2	Character specifying the column name of the class variable in the second dataset (default: "y")
version	Number in 1:3 specifying the version for calculating dataset similarity (default:1). See details.
tune	Should the decision tree parameters be tuned? (default: FALSE based on simulation results of Stolte et al. (2025))
k	Number of folds used in cross-validation for parameter tuning (default: 5). Ignored if tune = FALSE.
n.eval	Number of evaluations for random search used for parameter tuning (default: 100). Ignored if tune = FALSE.
seed	Random seed (default: NULL). A random seed will only be set if one is provided.
...	Further arguments passed to <code>rpart</code> . Ignored if tune = TRUE.

**Details**

*Ntoutsis et al. (2008)* define three measures of dataset similarity based on the intersection of the partitions of the sample space defined by the two decision trees fit to each dataset. Denote by  $\hat{P}_X(\mathcal{X})$  the proportion of observations in a dataset that fall into each segment of the joint partition and by  $P_X(Y, \mathcal{X})$  the proportion of observations in a dataset that fall into each segment of the joint partition and belong to each class.

$$s(p, q) = \sum_i \sqrt{p_i \cdot q_i}$$

defines the similarity index for two vectors  $p$  and  $q$ . Then the measures of similarity are defined by

$$\begin{aligned} \text{NTO1} &= s(\hat{P}_{X_1}(\mathcal{X}), \hat{P}_{X_2}(\mathcal{X})), \\ \text{NTO2} &= s(\hat{P}_{X_1}(Y, \mathcal{X}), \hat{P}_{X_2}(Y, \mathcal{X})), \\ \text{NTO3} &= S(Y|\mathcal{X})^T \hat{P}_{X_1 \cup X_2}(\mathcal{X}), \end{aligned}$$

where  $S(Y|\mathcal{X})$  is the similarity vector with elements

$$S(Y|\mathcal{X})_i = s(\hat{P}_{X_1}(Y|\mathcal{X})_{i\bullet}, \hat{P}_{X_2}(Y|\mathcal{X})_{i\bullet})$$

and index  $i\bullet$  denotes the  $i$ -th row.

The implementation uses `rpart` for fitting classification trees to each dataset.

`best.rpart` is used for hyperparameter tuning if `tune = TRUE`. The parameters are tuned using cross-validation and random search. The parameter `minsplits` is tuned over  $2^{(1:7)}$ , `minbucket` is tuned over  $2^{(0:6)}$  and `cp` is tuned over  $10^{\text{seq}(-4, -1, \text{by} = 0.001)}$ .

High values of each measure indicate similarity of the datasets. The measures are bounded between 0 and 1.

The chosen defaults are based on the simulation results of *Stolte et al. (2026)*.

**Value**

An object of class `htest` with the following components:

<code>statistic</code>	Observed value of the test statistic
<code>p.value</code>	NA (no p value calculated)
<code>method</code>	Description of the test
<code>data.name</code>	The dataset names
<code>alternative</code>	The alternative hypothesis

**Applicability**

Target variable?	Numeric?	Categorical?	K-sample?
Yes	Yes	No	No

**Note**

Because this method cannot handle missing data, any missing values are removed automatically and a warning is issued.

OTDD

*Optimal Transport Dataset Distance*

---

### Description

The function implements the optimal transport dataset distance (*Alvarez-Melis and Fusi, 2020*). The distance combines the distance between features and the distance between label distributions.

### Usage

```

OTDD(X1, X2, target1 = "y", target2 = "y", method = "precomputed.labeldist",
      feature.cost = stats::dist, lambda.x = 1, lambda.y = 1, p = 2, ground.p = 2,
      sinkhorn = FALSE, debias = FALSE, inner.ot.method = "exact", inner.ot.p = 2,
      inner.ot.ground.p = 2, inner.ot.sinkhorn = FALSE, inner.ot.debias = FALSE,
      seed = NULL)
hammingDist(x)

```

### Arguments

X1	First dataset as matrix or data.frame
X2	Second dataset as matrix or data.frame
target1	Character specifying the column name of the class variable in the first dataset (default: "y")
target2	Character specifying the column name of the class variable in the second dataset (default: "y")
method	Character specifying the method for computing the OTDD. Possible options are "augmentation", i.e. computing the optimal transport on the augmented dataset, and "precomputed.labeldist", i.e. the usual computation of label distances (default).
feature.cost	Function that calculates the distance matrix on the pooled feature dataset (default: <code>stats::dist</code> ). Ignored if <code>method = precomputed.labeldist</code> , then $L_p$ -distance is used as feature cost.
lambda.x, lambda.y	Weights of the feature distances and label distances in the overall cost (default: 1, equally weighted). Note that values unequal to one are only supported for <code>method = precomputed.labeldist</code> .
p	Power $p$ of the $p$ -Wasserstein distance for the outer optimal transport problem (default: 2).
ground.p	Power $p$ of the $L_p$ -norm used in calculation of Wasserstein distance for the outer optimal transport problem (default: 2). Ignored if <code>method = "precomputed.labeldist"</code> .

<code>sinkhorn</code>	Should the Sinkhorn approximation be used for solving the outer optimal transport problem? (default: FALSE, exact solution is used)
<code>debias</code>	Should debiased estimator be used when using Sinkhorn approximation for outer optimal transport problem? (default: FALSE)
<code>inner.ot.method</code>	Method for computing the label distances. Possible options are "exact" (the default), i.e. calculating the solution to the optimal transport of the label distributions, "gaussian.approx", i.e. calculating the Wasserstein distance of the labels using a Gaussian approximation of the label distributions, "naive.upperbound", i.e. calculating the upperbound $d_{UB}$ , "only.means", i.e. approximating the label distance by computing the Euclidean distance of the mean vectors of the label distributions. Ignored if method = "augmentation".
<code>inner.ot.p</code>	Power $p$ of the $p$ -Wasserstein distance for the inner optimal transport problem (default: 2). Used only if method = "precomputed.labeldist" and inner.ot.method = "exact".
<code>inner.ot.ground.p</code>	Power $p$ of the $L_p$ -norm used in calculation of Wasserstein distance for the outer optimal transport problem (default: 2). Used only if method = "precomputed.labeldist" and inner.ot.method = "exact".
<code>inner.ot.sinkhorn</code>	Should the Sinkhorn approximation be used for solving the inner optimal transport problem? (default: FALSE, exact solution is used). Used only if method = "precomputed.labeldist" and inner.ot.method = "exact".
<code>inner.ot.debias</code>	Should debiased estimator be used when using Sinkhorn approximation for inner optimal transport problem? (default: FALSE). Used only if method = "precomputed.labeldist" and inner.ot.method = "exact".
<code>seed</code>	Random seed (default: NULL). A random seed will only be set if one is provided.
<code>x</code>	Dataset for which the distance matrix of pairwise Hamming distances is calculated.

## Details

*Alvarez-Melis and Fusi (2020)* define a dataset distance that takes into account both the feature variables as well as a target (label) variable. The idea is to compute the optimal transport based on a cost function that is a combination of the feature distance and the Wasserstein distance between the label distributions. The label distribution refers to the distribution of features for a given label. With this, the distance between feature-label pairs  $z := (x, y)$  can be defined as

$$d_{\mathcal{Z}}(z, z') := (d_{\mathcal{X}}(x, x')^p + W_p^p(\alpha_y, \alpha_{y'}))^{1/p},$$

where  $\alpha_y$  denotes the distribution  $P(X|Y = y)$  for label  $y$  over the feature space. With this, the optimal transport dataset distance is defined as

$$d_{OT}(\mathcal{D}_1, \mathcal{D}_2) = \min_{\pi \in \Pi(\alpha, \beta)} \int_{\mathcal{Z} \times \mathcal{Z}} d_{\mathcal{Z}}(z, z')^p d\pi(z, z'),$$

where

$$\Pi(\alpha, \beta) := \{\pi_{1,2} \in \mathcal{P}(\mathcal{X} \times \mathcal{X}) \mid \pi_1 = \alpha, \pi_2 = \beta\}$$

is the set of joint distributions with  $\alpha$  and  $\beta$  as marginals.

Here, we use the Wasserstein distance implementation from the **approxOT** package for solving the optimal transport problems.

There are multiple simplifications implemented. First, under the assumption that the metric on the feature space coincides with the ground metric in the optimal transport problem on the labels and that all covariance matrices of the label distributions commute (rarely fulfilled in practice), the computation reduces to solving the optimal transport problem on the datasets augmented with the means and covariance matrices of the label distributions. This simplification is used when setting `method = "augmentation"`. Next, the Sinkhorn approximation can be utilized both for calculating the solution of the overall (outer) optimal transport problem (`sinkhorn = TRUE`) and for the inner optimal transport problem for computing the label distances (`inner.ot.sinkhorn = TRUE`). The solution of the inner problem can also be sped up by using a normal approximation of the label distributions (`inner.ot.method = "gaussian.approx"`) which results in a closed form expression of the solution. `inner.ot.method = "only.means"` further simplifies the calculation by using only the means of these Gaussians, which corresponds to assuming equal covariances in all Gaussian approximations of the label distributions. Using `inner.ot.method = "upper.bound"` uses a distribution-agnostic upper bound to bypass the solution of the inner optimal transport problem.

For categorical data, specify an appropriate `feature.cost` and use `method = "precomputed.labeldist"` and `inner.ot.method = "exact"`. A pre-implemented option is setting `feature.cost = hammingDist` for using the Hamming distance for categorical data. When implementing an appropriate function that takes the pooled dataset without the target column as input and gives a distance matrix as the output, a mix of categorical and numerical data is also possible.

## Value

An object of class `htest` with the following components:

<code>statistic</code>	Observed value of the test statistic
<code>method</code>	Description of the test
<code>data.name</code>	The dataset names
<code>alternative</code>	The alternative hypothesis

## Applicability

Target variable?	Numeric?	Categorical?	K-sample?
Yes	Yes	Yes	No

**Note**

Especially for large numbers of variables and low numbers of observations, it can happen that the Gaussian approximation of the inner OT problem fails since the estimated covariance matrix for one label distribution is numerically no longer psd. An error is thrown in that case.

Because this method cannot handle missing data, any missing values are removed automatically and a warning is issued.

---

 Petrie

*Multisample Crossmatch (MCM) Test*

---

## Description

Performs the multisample crossmatch (MCM) test (Petrie, 2016).

## Usage

```
Petrie(X1, X2, ..., dist.fun = stats::dist, dist.args = NULL, seed = NULL,
  shuffle = FALSE)
```

## Arguments

X1	First dataset as matrix or data.frame
X2	Second dataset as matrix or data.frame
...	Optionally more datasets as matrices or data.frames
dist.fun	Function for calculating a distance matrix on the pooled dataset (default: <code>stats::dist</code> , Euclidean distance).
dist.args	Named list of further arguments passed to <code>dist.fun</code> (default: <code>NULL</code> ).
seed	Random seed (default: <code>NULL</code> ). A random seed will only be set if one is provided.
shuffle	Logical indicator specifying whether the pooled sample should be randomly permuted before matching in the presence of ties (default: <code>FALSE</code> ).

## Details

The test is an extension of the *Rosenbaum (2005)* crossmatch test to multiple samples that uses the crossmatch count of all pairs of samples.

The observed cross-counts are calculated using the functions `distancematrix` and `nonbimatch` from the **nbpMatching** package.

High values of the multisample crossmatch statistic indicate similarity between the datasets. Thus, the test rejects the null hypothesis of equal distributions for low values of the test statistic.

Note that due to the specific implementation of the non-bipartite matching algorithm, inflated cross-counts in case of high numbers of ties in the distance matrix were observed in simulations under the null scenario, see note below. Therefore, the option to shuffle the dataset before the matching algorithm was introduced to circumvent this inflated cross-counts. A warning is thrown in case any ties in the distance matrix are detected.

## Value

An object of class `htest` with the following components:

<code>statistic</code>	Observed value of the test statistic
<code>p.value</code>	Asymptotic p value
<code>estimate</code>	Observed multisample edge-count
<code>alternative</code>	The alternative hypothesis
<code>method</code>	Description of the test
<code>data.name</code>	The dataset names
<code>stderr</code>	Standard deviation under the null
<code>mu0</code>	Expectation under the null

## Applicability

Target variable?	Numeric?	Categorical?	K-sample?
No	Yes	Yes	Yes

## Note

In case of ties in the distance matrix, the optimal non-bipartite matching might not be defined uniquely. Here, the observations are matched in the order in which the samples are supplied. When searching for a match, the implementation starts at the end of the pooled sample. Therefore, with many ties (e.g. for categorical data), observations from the first dataset are often matched with ones from the last dataset and so on. This might affect the validity of the test negatively. For this reason, a warning is issued whenever ties are detected. As a workaround, users can set `shuffle = TRUE` in the function call, which randomly permutes the pooled sample before matching. When using this option, it is strongly recommended to set a random seed to ensure reproducibility.

Because this method cannot handle missing data, any missing values are removed automatically and a warning is issued.

rectPartition

*Calculate a Rectangular Partition*

---

## Description

The function calculates a rectangular partition of the subspace spanned by the data. Used for [BG](#).

## Usage

```
rectPartition(X1, X2, n, p, exponent = 0.8, eps = 0.01)
```

**Arguments**

X1	First dataset as matrix
X2	Second dataset as matrix
n	Number of rows in the data
p	Number of columns in the data
exponent	Exponent to ensure coverage criteria, should be between 0 and 1 (default: 0.8)
eps	Small threshold to guarantee edge points are included (default: 0.01)

**Value**

A list with the following components:

A	A list of $p$ elements containing the partition cutpoints for every dimension
m_n	Total number of elements in the partition
m_n_d	Number of partition elements per dimension

RISE

*Rank In Similarity Graph Edge-count two-sample test (RISE)***Description**

Performs the Rank In Similarity Graph Edge-count two-sample test (RISE) for multivariate data (Zhou and Chen, 2023). The implementation here uses the RISE implementation from the **GraphRank-Test** package.

**Usage**

```
RISE(X1, X2, sim.fun = function(x, ...) -as.matrix(stats::dist(x, ...)), K = 10,
     rank.type = "RgNN", n.perm = 0, dist.args = NULL, seed = NULL)
```

**Arguments**

X1	First dataset as matrix or data.frame
X2	Second dataset as matrix or data.frame
sim.fun	Function for calculating a similarity matrix on the pooled dataset (default: negative value of <code>stats::dist</code> , Euclidean distance).
K	Parameter $K$ of the chosen graph (default: 10). Must be a positive number.
rank.type	Character specifying the similarity graph ( $K$ -nearest neighbor graph, $K$ -NN; $K$ -minimum spanning tree, $K$ -MST; $K$ -minimum-distance non-bipartite matching, $K$ -MDP) and the rank definition (graph-induced ranks, Rg; overall ranks, Ro; see Details). Possible options are all combinations of the aforementioned options: "RgNN" (default), "RoNN", "RgMST", "RoMST", "RgMDP", "RoMDP".
n.perm	Number of permutations for permutation test (default: 0, asymptotic test is performed).
dist.args	Named list of further arguments passed to <code>dist.fun</code> (default: NULL).
seed	Random seed (default: NULL). A random seed will only be set if one is provided.

**Details**

Zhou and Chen, 2023 define the following two graph-based rank matrices  $R = (R_{ij})_{i,j=1}^N$  using sequences of similarity graphs  $G_l$  based on the distance matrix  $S$  of the two datasets. The *graph-induced ranks* are defined as

$$R_{ij} = \sum_{l=1}^K \mathbf{1}((i, j) \in G_l).$$

They can be interpreted as the number of graphs that contain the edge  $(i, j)$  in the sequence of graphs. The *overall ranks* are defined as

$$R_{ij} = \text{rank}(S(Z_i, Z_j), G_K),$$

where  $\text{rank}(S(Z_i, Z_j), G_K)$  denotes the rank of  $S(Z_i, Z_j)$  among the values  $\{S(Z_u, Z_v)\}_{(u,v) \in G_K}$  if  $(i, j) \in G_k$  and zero otherwise. The overall rank can be interpreted as the rank of the similarity of edges in the graph  $G_K$ . Both rank definitions depend on the choice of the parameter  $K$  that defines the length of the graph sequence. For the test, the symmetrized rank matrix  $1/2(R + R^T)$  is used, which is also denoted by  $\$R\$$  for convenience.

For the test statistic, the within-sample rank sums of the first and second sample are defined as

$$U_x = \sum_{i,j=1}^{n_1} R_{ij}, U_y = \sum_{i,j=n_1+1}^N R_{ij}.$$

Using these, the *rank in similarity graph edge-count two-sample test (RISE)* statistic is defined as

$$T_R = (U_{X1} - \mu_{X1}, U_{X2} - \mu_{X2}) \Sigma^{-1} (U_{X1} - \mu_{X1}, U_{X2} - \mu_{X2})^T,$$

where  $\mu_{X1} = \mathbb{E}(U_{X1})$ ,  $\mu_{X2} = \mathbb{E}(U_{X2})$ , and  $\Sigma = \text{Cov}((U_{X1}, U_{X2})^T)$  can be calculated explicitly under the permutation null hypothesis.

For small samples, the exact permutation null distribution can be used for testing. For large samples and under several assumptions on the similarity graphs, the asymptotic  $\chi^2_2$ -distribution of  $T_R$  can be used for testing.

High values of the test statistic indicate dissimilarity of the datasets. Thus, the null hypothesis of equal distributions is rejected for large values.

For  $n.\text{perm} = 0$ , an asymptotic test using the asymptotic  $\chi^2_2$  approximation of the null distribution is performed. For  $n.\text{perm} > 0$ , a permutation test is performed.

This implementation is a wrapper function around the function [RISE](#) that modifies the in- and output of that function to match the other functions provided in this package. For more details see the [RISE](#).

## Value

An object of class `htest` with the following components:

<code>statistic</code>	Observed value of the test statistic
<code>parameter</code>	Degrees of freedom for asymptotic test
<code>p.value</code>	Asymptotic or permutation p value
<code>alternative</code>	The alternative hypothesis
<code>method</code>	Description of the test
<code>data.name</code>	The dataset names

## Applicability

Target variable?	Numeric?	Categorical?	K-sample?
No	Yes	No	No

**Note**

Because this method cannot handle missing data, any missing values are removed automatically and a warning is issued.

---

RItest

*Multisample RI Test*

---

**Description**

Performs the (modified/ multiscale/ aggregated) RI test (*Paul et al., 2021*). The implementation is based on the [RItest](#), [MTRItest](#), and [ARItest](#) implementations from the **HDLSSkST** package.

**Usage**

```
RItest(X1, X2, ..., n.clust, randomization = TRUE, version = "original",
       mult.test = "Holm", kmax = 2 * n.clust, s.psi = 3, s.h = 1,
       lb = 1, n.perm = 1/alpha, alpha = 0.05, seed = NULL)
```

**Arguments**

X1	First dataset as matrix or data.frame
X2	Second dataset as matrix or data.frame
...	Optionally more datasets as matrices or data.frames

n.clust	Number of clusters (only applicable for version = "original").
randomization	Should a randomized test be performed? (default: TRUE, randomized test is performed)
version	Which version of the test should be performed? Possible options are "original" (default) for the FS test, "modified" for the MFS test (number of clusters is estimated), "multiscale" for the MSFS test (all numbers of clusters up to kmax are tried and results are summarized), "aggregated-knw" (all pairwise comparisons are tested with the FS test and results are aggregated), and "aggregated-est" (all pairwise comparisons are tested with the MFS test and results are aggregated).
mult.test	Multiple testing adjustment for AFS test and MSFS test. Possible options are "Holm" (default) and "BenHoch".
kmax	Maximum number of clusters to try for estimating the number of clusters (default: 2*n.clust).
s.psi	Numeric code for function required for calculating the distance for $K$ -means clustering. The value 1 corresponds to $\psi(t) = t^2$ (the default), 2 corresponds to $\psi(t) = 1 - \exp(-t)$ , 3 corresponds to $\psi(t) = 1 - \exp(-t^2)$ , 4 corresponds to $\psi(t) = \log(1 + t)$ , 5 corresponds to $\psi(t) = t$ .
s.h	Numeric code for function required for calculating the distance for $K$ -means clustering. The value 1 corresponds to $h(t) = \sqrt{t}$ (the default), and 2 corresponds to $h(t) = t$ .
lb	Length of smaller vectors into which each observation is partitioned (default: 1).
n.perm	Number of simulations of the test statistic (default: 1/alpha, minimum number required for running the test, set to a higher value for meaningful test results).
alpha	Test level (default: 0.05).
seed	Random seed (default: NULL). A random seed will only be set if one is provided.

## Details

The tests are intended for the high dimension low sample size (HDLSS) setting. The idea is to cluster the pooled sample using a clustering algorithm that is suitable for the HDLSS setting and then to compare the clustering to the true dataset membership using the Rand index. For the original RI test, the number of clusters has to be specified. If no number is specified it is set to the number of samples. This is a reasonable number of clusters in many cases.

However, in some cases, different numbers of clusters might be needed. For example in case of multimodal distributions in the datasets, there might be multiple clusters within each dataset. Therefore, the modified (MRI) test allows to estimate the number of clusters from the data.

In case of a really unclear number of clusters, the multiscale (MSRI) test can be applied which calculates the test for each number of clusters up to kmax and then summarizes the test results using some adjustment for multiple testing.

These three tests take into account all samples simultaneously. The aggregated (ARI) test instead performs all pairwise FS or MFS tests on the samples and aggregates those results by taking the minimum test statistic value and applying a multiple testing procedure.

For clustering, a  $K$ -means algorithm using the generalized version of the Mean Absolute Difference of Distances (MADD) (Sarkar and Ghosh, 2020) is applied. The MADD is defined as

$$\rho_{h,\varphi}(z_i, z_j) = \frac{1}{N-2} \sum_{m \in \{1, \dots, N\} \setminus \{i, j\}} |\varphi_{h,\psi}(z_i, z_m) - \varphi_{h,\psi}(z_j, z_m)|,$$

where  $z_i \in \mathbb{R}^p$ ,  $i = 1, \dots, N$ , denote points from the pooled sample and

$$\varphi_{h,\psi}(z_i, z_j) = h \left( \frac{1}{p} \sum_{l=1}^p \psi |z_{il} - z_{jl}| \right),$$

with  $h : \mathbb{R}^+ \rightarrow \mathbb{R}^+$  and  $\psi : \mathbb{R}^+ \rightarrow \mathbb{R}^+$  continuous and strictly increasing functions. The functions  $h$  and  $\psi$  can be set via changing `s.psi` and `s.h`.

In all cases, high values of the test statistic correspond to similarity between the datasets. Therefore, the null hypothesis of equal distributions is rejected for low values.

The chosen defaults are based on the simulation results of Stolte et al. (2026).

It should be noted that the best choices for `s.psi` and `s.h` differed widely depending on the distribution of the data and the alternative of interest. Refer to the detailed simulation results for more information.

This implementation is a wrapper function around the function `RIttest` that modifies the in- and output of that function to match the other functions provided in this package. For more details see `RIttest`.

## Value

An object of class `htest` with the following components:

<code>statistic</code>	Observed value of the test statistic
<code>p.value</code>	Asymptotic p value
<code>alternative</code>	The alternative hypothesis
<code>method</code>	Description of the test
<code>data.name</code>	The dataset names
<code>est.cluster.label</code>	The estimated cluster label (not for AFS and MSFS)
<code>observed.cont.table</code>	The observed contingency table of dataset membership and estimated cluster label (not for AFS)
<code>crit.value</code>	The critical value of the test (not for MSFS)
<code>random.gamma</code>	The randomization constant of the test (not for MSFS)
<code>decision</code>	The (overall) test decision
<code>decision.per.k</code>	The test decisions of all individual tests (only for MSFS)
<code>est.cluster.no</code>	The estimated number of clusters (not for MSFS)

**Applicability**

Target variable?	Numeric?	Categorical?	K-sample?
No	Yes	No	Yes

**Note**

In case of `version = "multiscale"` the output is a list object and not of class `htest` as there are multiple test statistic values and corresponding p values.

Note that the aggregated test cannot handle univariate data.

Because this method cannot handle missing data, any missing values are removed automatically and a warning is issued.

Rosenbaum

*Rosenbaum Crossmatch Test*

---

### Description

Performs the *Rosenbaum (2005)* crossmatch two-sample test. The implementation here uses the [crossmatchtest](#) implementation from the **crossmatch** package.

### Usage

```
Rosenbaum(X1, X2, exact = FALSE, dist.fun = stats::dist, dist.args = NULL, seed = NULL)
```

### Arguments

X1	First dataset as matrix or data.frame
X2	Second dataset as matrix or data.frame
exact	Should the exact null distribution be used? (default: FALSE). The exact distribution calculation is only possible for a pooled sample size of less than 340 due to numerical reasons. If exact = FALSE or the sample size limit is reached, an asymptotic test is performed.
dist.fun	Function for calculating a distance matrix on the pooled dataset (default: <a href="#">stats::dist</a> , Euclidean distance).
dist.args	Named list of further arguments passed to <code>dist.fun</code> (default: NULL).
seed	Random seed (default: NULL). A random seed will only be set if one is provided.

### Details

The test statistic is calculated as the standardized number of edges connecting points from different samples in a non-bipartite matching. The non-bipartite matching is calculated using the implementation from the [nbpMatching](#) package. The null hypothesis of equal distributions is rejected for small values of the test statistic as high values of the crossmatch statistic indicate similarity between datasets.

This implementation is a wrapper function around the function [crossmatchtest](#) that modifies the in- and output of that function to match the other functions provided in this package. For more details see [crossmatchtest](#).

**Value**

An object of class `htest` with the following components:

<code>statistic</code>	Observed value of the test statistic
<code>p.value</code>	Asymptotic p value
<code>estimate</code>	Unstandardized crossmatch count
<code>alternative</code>	The alternative hypothesis
<code>method</code>	Description of the test
<code>data.name</code>	The dataset names
<code>stderr</code>	Standard deviation of the test statistic under the null
<code>mu0</code>	Expectation of the test statistic under the null

**Applicability**

Target variable?	Numeric?	Categorical?	K-sample?
No	Yes	No	No

**Note**

Because this method cannot handle missing data, any missing values are removed automatically and a warning is issued.

 SC

*Graph-Based Multi-Sample Test*

---

## Description

Performs the graph-based multi-sample test for high-dimensional data proposed by *Song and Chen (2022)*. The implementation here uses the `gtestsmulti` implementation from the `gTestsMulti` package.

## Usage

```
SC(X1, X2, ..., n.perm = 0, dist.fun = stats::dist, graph.fun = MST5,
  dist.args = NULL, graph.args = NULL, type = "SA", seed = NULL)
```

## Arguments

<code>X1</code>	First dataset as matrix or data.frame
<code>X2</code>	Second dataset as matrix or data.frame
<code>...</code>	Optionally more datasets as matrices or data.frames
<code>n.perm</code>	Number of permutations for permutation test (default: 0, no permutation test performed)
<code>dist.fun</code>	Function for calculating a distance matrix on the pooled dataset (default: <code>stats::dist</code> , Euclidean distance).
<code>graph.fun</code>	Function for calculating a similarity graph using the distance matrix on the pooled sample (default: <code>MST5</code> , 5-Minimum Spanning Tree).
<code>dist.args</code>	Named list of further arguments passed to <code>dist.fun</code> (default: <code>NULL</code> ).
<code>graph.args</code>	Named list of further arguments passed to <code>graph.fun</code> (default: <code>NULL</code> ).
<code>type</code>	Character specifying the test statistic to use. Possible options are "S" and "SA" (default). See details.
<code>seed</code>	Random seed (default: <code>NULL</code> ). A random seed will only be set if one is provided.

**Details**

Two multi-sample test statistics are defined by *Song and Chen (2022)* based on a similarity graph. The first one is defined as

$$S = S_W + S_B, \text{ where}$$

$$S_W = (R_W - E(R_W))^T \Sigma_W^{-1} (R_W - E(R_W)),$$

$$S_B = (R_B - E(R_B))^T \Sigma_W^{-1} (R_B - E(R_B)),$$

with  $R_W$  denoting the vector of within-sample edge counts and  $R_B$  the vector of between-sample edge counts. Expectations and covariance matrix are calculated under the null.

The second statistic is defined as

$$S_A = (R_A - E(R_A))^T \Sigma_W^{-1} (R_A - E(R_A)),$$

where  $R_A$  is the vector of all linearly independent edge counts, i.e. the edge counts for all pairs of samples except the last pair  $k - 1$  and  $k$ .

This implementation is a wrapper function around the function `gtestsmulti` that modifies the in- and output of that function to match the other functions provided in this package. For more details see the `gtestsmulti`.

**Value**

An object of class `htest` with the following components:

<code>statistic</code>	Observed value of the test statistic
<code>p.value</code>	Permutation p value (only if <code>n.perm &gt; 0</code> )
<code>estimate</code>	Estimated KMD value
<code>alternative</code>	The alternative hypothesis
<code>method</code>	Description of the test
<code>data.name</code>	The dataset names

**Applicability**

Target variable?	Numeric?	Categorical?	K-sample?
No	Yes	No	Yes

**Note**

Because this method cannot handle missing data, any missing values are removed automatically and a warning is issued.

}
```

---

 SH

*Schilling-Henze Nearest Neighbor Test*

---

## Description

Performs the Schilling-Henze two-sample test for multivariate data (*Schilling, 1986; Henze, 1988*).

## Usage

```
SH(X1, X2, K = 5, graph.fun = knn.bf, dist.fun = stats::dist, n.perm = 0,
  dist.args = NULL, seed = NULL)
```

## Arguments

X1	First dataset as matrix or data.frame
X2	Second dataset as matrix or data.frame
K	Number of nearest neighbors to consider (default: 5)
graph.fun	Function for calculating a similarity graph using the distance matrix on the pooled sample (default: <a href="#">knn.bf</a> which searches for the K nearest neighbors by ranking all pairwise distances, alternative: <a href="#">knn</a> which is a wrapper for extracting the edge matrix from the result of <a href="#">knn</a> in <a href="#">dbscan</a> , <a href="#">knn.fast</a> which is a wrapper for the approximative KNN implementation <a href="#">get.knn</a> in <a href="#">FNN</a> , or any other function that calculates the KNN edge matrix from a distance matrix and the number of nearest neighbors K).

<code>dist.fun</code>	Function for calculating a distance matrix on the pooled dataset (default: <code>stats::dist</code> , Euclidean distance).
<code>n.perm</code>	Number of permutations for permutation test (default: 0, asymptotic test is performed).
<code>dist.args</code>	Named list of further arguments passed to <code>dist.fun</code> .
<code>seed</code>	Random seed (default: NULL). A random seed will only be set if one is provided.

### Details

The test statistic is the proportion of edges connecting points from the same dataset in a K-nearest neighbor graph calculated on the pooled sample (standardized with expectation and SD under the null).

Low values of the test statistic indicate similarity of the datasets. Thus, the null hypothesis of equal distributions is rejected for high values.

For  $n.perm = 0$ , an asymptotic test using the asymptotic normal approximation of the conditional null distribution is performed. For  $n.perm > 0$ , a permutation test is performed.

### Value

An object of class `htest` with the following components:

<code>statistic</code>	Observed value of the test statistic
<code>p.value</code>	Asymptotic or permutation p value
<code>estimate</code>	The number of within-sample edges
<code>alternative</code>	The alternative hypothesis
<code>method</code>	Description of the test
<code>data.name</code>	The dataset names

### Applicability

Target variable?	Numeric?	Categorical?	K-sample?
No	Yes	No	No

### Note

The default for K is chosen based on simulation results of *Stolte et al. (2026)*. Note that still there is little guidance on the choice of K. Typical values for K chosen in the literature are 1 and 5.

Because this method cannot handle missing data, any missing values are removed automatically and a warning is issued.

stat.fun

*Univariate Two-Sample Statistics for DiProPerm Test*

---

## Description

Helper functions for calculating univariate two-sample statistic for the Direction-Projection-Permutation (DiProPerm) two-sample test for high-dimensional data (Wei *et al.*, 2016)

## Usage

```
MD(x1, x2)
tStat(x1, x2)
AUC(x1, x2)
```

## Arguments

`x1` Numeric vector of scores for the first sample.  
`x2` Numeric vector of scores for the second sample.

## Details

The DiProPerm test works by first combining the datasets into a pooled dataset and creating a target variable with the dataset membership of each observation. A binary linear classifier is then trained on the class labels and the normal vector of the separating hyperplane is calculated. The data from both samples is projected onto this normal vector. This gives a scalar score for each observation. On these projection scores, a univariate two-sample statistic is calculated. The permutation null distribution of this statistic is calculated by permuting the dataset labels and repeating the whole procedure with the permuted labels. The functions here correspond to the univariate two-sample statistics suggested in the original article of *Wei et al., 2016*.

## Value

A numeric scalar giving the observed two-sample statistic value.

---

Wasserstein

*Wasserstein Distance Based Test*

---

### Description

Performs a permutation two-sample test based on the Wasserstein distance. The implementation here uses the `wasserstein_permut` implementation from the **Ecume** package.

### Usage

```

Wasserstein(X1, X2, n.perm = 0, fast = (nrow(X1) + nrow(X2)) > 1000,
            S = max(1000, (nrow(X1) + nrow(X2))/2), seed = NULL, ...)

```

### Arguments

X1	First dataset as matrix or data.frame
X2	Second dataset as matrix or data.frame
n.perm	Number of permutations for permutation test (default: 0, no test is performed).
fast	Should the <code>subwasserstein</code> approximate function be used? (default: TRUE if the pooled sample size is more than 1000)
S	Number of samples to use for approximation if fast = TRUE. See <code>subwasserstein</code>
seed	Random seed (default: NULL). A random seed will only be set if one is provided.
...	Other parameters passed to <code>wasserstein</code> or <code>wasserstein1d</code> , e.g. the power $p \geq 1$

### Details

A permutation test for the  $p$ -Wasserstein distance is performed. By default, the 1-Wasserstein distance is calculated using Euclidean distances. The  $p$ -Wasserstein distance between two probability measures  $\mu$  and  $\nu$  on a Euclidean space  $M$  is defined as

$$W_p(\mu, \nu) = \left( \inf_{\gamma \in \Gamma(\mu, \nu)} \int_{M \times M} \|x - y\|^p d\gamma(x, y) \right)^{\frac{1}{p}},$$

where  $\Gamma(\mu, \nu)$  is the set of probability measures on  $M \times M$  such that  $\mu$  and  $\nu$  are the marginal distributions.

As the Wasserstein distance of two distributions is a metric, it is zero if and only if the distributions coincides. Therefore, low values of the statistic indicate similarity of the datasets and the test rejects for high values.

This implementation is a wrapper function around the function `wasserstein_permut` that modifies the in- and output of that function to match the other functions provided in this package. For more details see the `wasserstein_permut`.

Note that only datasets with the same number of observations are supported.

### Value

An object of class `htest` with the following components:

<code>statistic</code>	Observed value of the test statistic
<code>p.value</code>	Asymptotic p value
<code>alternative</code>	The alternative hypothesis
<code>method</code>	Description of the test
<code>data.name</code>	The dataset names

### Applicability

Target variable?	Numeric?	Categorical?	K-sample?
No	Yes	No	No

### Note

Because this method cannot handle missing data, any missing values are removed automatically and a warning is issued. This may lead to an unequal number of observations in the datasets.

 YMRZL

*Yu et al. (2007) Two-Sample Test*

---

## Description

Performs the *Yu et al. (2007)* two-sample test. The implementation here uses the `classifier_test` implementation from the **Ecume** package.

## Usage

```
YMRZL(X1, X2, n.perm = 0, split = 0.7, control = NULL,
      train.args = NULL, seed = NULL)
```

## Arguments

<code>X1</code>	First dataset as matrix or data.frame
<code>X2</code>	Second dataset as matrix or data.frame
<code>n.perm</code>	Number of permutations for permutation test (default: 0, asymptotic test is performed).
<code>split</code>	Proportion of observations used for training
<code>control</code>	Control parameters for fitting. See <code>trainControl</code> . Defaults to <code>caret::trainControl(method = "boot")</code> as recommended if <code>control = NULL</code> . The number of Bootstrap samples defaults to 25 and can be set by specifying the number argument of <code>caret::trainControl</code> .
<code>train.args</code>	Further arguments passed to <code>train</code> as a named list.
<code>seed</code>	Random seed (default: NULL). A random seed will only be set if one is provided.

## Details

The two-sample test proposed by *Yu et al. (2007)* works by first combining the datasets into a pooled dataset and creating a target variable with the dataset membership of each observation. The pooled sample is then split into training and test set and a classification tree is trained on the training data. The test classification error is then used as a test statistic. If the distributions of the datasets do not differ, the classifier will be unable to distinguish between the datasets and therefore the test error will be close to chance level. The test rejects if the test error is smaller than chance level.

The tree model is fit by `rpart` and the classification error for tuning is by default predicted using the Bootstrap .632+ estimator as recommended by *Yu et al. (2007)*.

For  $n.\text{perm} > 0$ , a permutation test is conducted. Otherwise, an asymptotic binomial test is performed.

### Value

An object of class `htest` with the following components:

<code>statistic</code>	Observed value of the test statistic
<code>p.value</code>	Asymptotic p value
<code>alternative</code>	The alternative hypothesis
<code>method</code>	Description of the test
<code>data.name</code>	The dataset names
<code>classifier</code>	Chosen classification method (tree)

### Applicability

Target variable?	Numeric?	Categorical?	K-sample?
No	Yes	Yes	No

### Note

As the idea of the test is very similar to that of the classifier two-sample test by *Lopez-Paz and Oquab (2022)*, the implementation here is based on that `C2ST`. Note that *Lopez-Paz and Oquab (2022)* utilize the classification accuracy instead of the classification error. Moreover, they propose to use a binomial test instead of the permutation test proposed by *Yu et al.*. Here, we implemented both the binomial and the permutation test.

Because this method cannot handle missing data, any missing values are removed automatically and a warning is issued.

ZC

*Maxtype Edge-Count Test*

---

### Description

Performs the maxtype edge-count two-sample test for multivariate data proposed by *Zhang and Chen (2017)*. The implementation here uses the [g.tests](#) implementation from the **gTests** package.

### Usage

```
ZC(X1, X2, dist.fun = stats::dist, graph.fun = MST5, n.perm = 0,
  dist.args = NULL, graph.args = NULL, maxtype.kappa = 1, seed = NULL)
```

### Arguments

X1	First dataset as matrix or data.frame
X2	Second dataset as matrix or data.frame
dist.fun	Function for calculating a distance matrix on the pooled dataset (default: <a href="#">stats::dist</a> , Euclidean distance).
graph.fun	Function for calculating a similarity graph using the distance matrix on the pooled sample (default: <a href="#">MST5</a> , 5-Minimum Spanning Tree).
n.perm	Number of permutations for permutation test (default: 0, asymptotic test is performed).
dist.args	Named list of further arguments passed to <code>dist.fun</code> (default: NULL).
graph.args	Named list of further arguments passed to <code>graph.fun</code> (default: NULL).
maxtype.kappa	Parameter $\kappa$ of the test (default: 1). See details.
seed	Random seed (default: NULL). A random seed will only be set if one is provided.

## Details

The test is an enhancement of the Friedman-Rafsky test (original edge-count test) that aims at detecting both location and scale alternatives and is more flexible than the generalized edge-count test of Chen and Friedman (2017). The test statistic is the maximum of two statistics. The first statistic is the weighted edge-count statistic multiplied by a factor  $\kappa$ . The second statistic is the absolute value of the standardized difference of edge-counts within the first and within the second sample.

Low values of the test statistic indicate similarity of the datasets. Thus, the null hypothesis of equal distributions is rejected for high values.

For  $n.\text{perm} = 0$ , an asymptotic test using the asymptotic normal approximation of the null distribution is performed. For  $n.\text{perm} > 0$ , a permutation test is performed.

This implementation is a wrapper function around the function `g.tests` that modifies the in- and output of that function to match the other functions provided in this package. For more details see the `g.tests`.

The chosen defaults are based on the simulation results of *Stolte et al. (2026)*.

## Value

An object of class `htest` with the following components:

<code>statistic</code>	Observed value of the test statistic
<code>p.value</code>	Asymptotic or permutation p value
<code>alternative</code>	The alternative hypothesis
<code>method</code>	Description of the test
<code>data.name</code>	The dataset names

## Applicability

Target variable?	Numeric?	Categorical?	K-sample?
No	Yes	No	No

## Note

Because this method cannot handle missing data, any missing values are removed automatically and a warning is issued.

  ZC(X1, X2, graph.fun = MST, graph.args = list(K = 3))
}
```

---

ZC\_cat

*Maxtype Edge-Count Test for Discrete Data*

---

### Description

Performs the maxtype edge-count two-sample test for multivariate data proposed by *Zhang and Chen (2022)*. The implementation here uses the [g.tests](#) implementation from the [gTests](#) package.

### Usage

```
ZC_cat(X1, X2, dist.fun, agg.type = "u", graph.type = "mstree", K = 5, n.perm = 0,
maxtype.kappa = 1.14, seed = NULL)
```

### Arguments

X1	First dataset as matrix or data.frame
X2	Second dataset as matrix or data.frame
dist.fun	Function for calculating the distance of the unique observations. Should take a dataset of the same format as X1 or X2 as its input and return a distance matrix of the pairwise distances in that dataset. Should be appropriate for handling the scale level of the variables present in X1 and X2, e.g. <a href="#">hammingDist</a> for nominal variables, appropriate distances for ordinal data or the Gower distance for mixed nominal and ordinal data.

<code>agg.type</code>	Character giving the method for aggregating over possible similarity graphs. Options are "u" (default) for union of possible similarity graphs and "a" for averaging over test statistics calculated on possible similarity graphs.
<code>graph.type</code>	Character specifying which similarity graph to use. Possible options are "mstree" (default, Minimum Spanning Tree) and "nnlink" (Nearest Neighbor Graph).
<code>K</code>	Parameter for graph (default: 5). If <code>graph.type = "mstree"</code> , a K-MST is constructed (K=1 is the classical MST). If <code>graph.type = "nnlink"</code> , K gives the number of neighbors considered in the K-NN graph.
<code>n.perm</code>	Number of permutations for permutation test (default: 0, asymptotic test is performed).
<code>maxtype.kappa</code>	Parameter $\kappa$ of the test (default: 1.14). See details.
<code>seed</code>	Random seed (default: NULL). A random seed will only be set if one is provided.

## Details

The test is an enhancement of the Friedman-Rafsky test (original edge-count test) that aims at detecting both location and scale alternatives and is more flexible than the generalized edge-count test of *Chen and Friedman (2017)*. The test statistic is the maximum of two statistics. The first statistic is the weighted edge-count statistic multiplied by a factor  $\kappa$ . The second statistic is the absolute value of the standardized difference of edge-counts within the first and within the second sample.

Low values of the test statistic indicate similarity of the datasets. Thus, the null hypothesis of equal distributions is rejected for high values.

For discrete data, the similarity graph used in the test is not necessarily unique. This can be solved by either taking a union of all optimal similarity graphs or averaging the test statistics over all optimal similarity graphs. For details, see *Zhang and Chen (2017)*.

For `n.perm = 0`, an asymptotic test using the asymptotic normal approximation of the null distribution is performed. For `n.perm > 0`, a permutation test is performed.

The chosen defaults are based on the simulation results of *Stolte et al. (2025)*.

This implementation is a wrapper function around the function `g.tests` that modifies the in- and output of that function to match the other functions provided in this package. For more details see the `g.tests`.

## Value

An object of class `htest` with the following components:

<code>statistic</code>	Observed value of the test statistic
<code>p.value</code>	Asymptotic or permutation p value
<code>alternative</code>	The alternative hypothesis
<code>method</code>	Description of the test
<code>data.name</code>	The dataset names

## Applicability

Target variable?	Numeric?	Categorical?	K-sample?
No	No	Yes	No

## Note

Because this method cannot handle missing data, any missing values are removed automatically and a warning is issued.
