

Package ‘Spower’

May 21, 2026

Title Power Analyses using Monte Carlo Simulations

Version 0.6.3

Description Provides a general purpose simulation-based power analysis API for routine and customized simulation experimental designs. The package focuses exclusively on Monte Carlo simulation experiment variants of (expected) prospective power analyses, criterion analyses, compromise analyses, sensitivity analyses, and a priori/post-hoc analyses. The default simulation experiment functions defined within the package provide stochastic variants of the power analysis subroutines in G*Power 3.1 (Faul, Erdfelder, Buchner, and Lang, 2009) <doi:10.3758/brm.41.4.1149>, along with various other parametric and non-parametric power analysis applications (e.g., mediation analyses) and support for Bayesian power analysis by way of Bayes factors or posterior probability evaluations. Additional functions for building empirical power curves, reanalyzing simulation information, and for increasing the precision of the resulting power estimates are also included, each of which utilize similar API structures. For further details see the associated publication in Chalmers (2025) <doi:10.3758/s13428-025-02787-z>.

Depends SimDesign (>= 2.22.3), R (>= 4.1.0), stats

Imports cocor, car, polycor, parallelly, mirai, methods, cli, ggplot2, plotly, lavaan, EnvStats

Suggests knitr, rmarkdown, bookdown, extraDistr, copula, effectsize, pwr

VignetteBuilder knitr

ByteCompile yes

getLastSpower	<i>Get previously evaluated Spower execution</i>
---------------	--

Description

If the result of `Spower` or `SpowerBatch` was not stored into an object this function will retrieve the last evaluation.

Usage

```
getLastSpower()
```

Value

the last object returned from [Spower](#) or [SpowerBatch](#)

Author(s)

Phil Chalmers <rphilip.chalmers@gmail.com>

is.CI_within	<i>Evaluate whether a confidence interval is within a tolerable interval</i>
--------------	--

Description

Return TRUE if an estimated confidence interval falls within a tolerable interval range. Typically used for equivalence, superiority, or non-inferiority testing.

Usage

```
is.CI_within(CI, interval)
```

Arguments

CI	estimated confidence interval (length 2)
interval	tolerable interval range (length 2)

Value

logical

Author(s)

Phil Chalmers <rphilip.chalmers@gmail.com>

See Also

[is.outside_CI](#), [Spower](#)

Examples

```

CI <- c(.2, .4)
LU <- c(.1, .3)
is.CI_within(CI, LU)      # not within tolerable interval
is.CI_within(CI, c(0, .5)) # is within wider interval

# complement indicates if CI is outside interval
!is.CI_within(CI, LU)

#####
# for superiority test
is.CI_within(CI, c(.1, Inf)) # CI is within tolerable interval

# for inferiority test
is.CI_within(CI, c(-Inf, .3)) # CI is not within tolerable interval

```

is.outside_CI	<i>Evaluate whether parameter is outside a given confidence interval</i>
---------------	--

Description

Returns TRUE if parameter reflecting a null hypothesis falls outside a given confidence interval. This is an alternative approach to writing an experiment that returns a p-value.

Usage

```
is.outside_CI(P0, CI)
```

Arguments

P0	parameter to evaluate
CI	confidence interval

Value

logical

Author(s)

Phil Chalmers <rphilip.chalmers@gmail.com>

See Also

[is.CI_within](#), [Spower](#)

Examples

```
p0 <- .3
CI <- c(.2, .4)
is.outside_CI(p0, CI)

# complement indicates if p0 is within CI
!is.outside_CI(p0, CI)
```

p_2r

*p-value from comparing two or more correlations simulation***Description**

Function utilizes [cocor](#) to perform correlation comparison for independent, overlapping, and non-overlapping correlation designs. Type of correlation design is inferred based on which correlations are specified.

Usage

```
p_2r(
  n,
  r.ab,
  r.ab2 = NULL,
  r.ac,
  r.bc,
  r.ad,
  r.bd,
  r.cd,
  n2_n1 = 1,
  two.tailed = TRUE,
  test = NULL,
  gen_fun = gen_2r,
  return_analysis = FALSE,
  ...
)

gen_2r(n, R, ...)
```

Arguments

n	sample size
r.ab	correlation between variable A and B (for independent groups, this is for sample 1)
r.ab2	(for independent group test only) correlation between variable A and B in sample 2

r.ac	(for overlap/non-overlap) correlation between A and C. This is the correlation used in the overlapping hypothesis test, comparing this input to r.ab
r.bc	(for overlap/non-overlap only) correlation between B and C.
r.ad	(for non-overlap only) correlation between A and D
r.bd	(for non-overlap only) correlation between B and D
r.cd	(for non-overlap only) correlation between C and D. This is the correlation used in the non-overlapping hypothesis test, comparing this input to r.ab
n2_n1	sample size ratio. Only used for independent group test
two.tailed	logical; use two-tailed test?
test	hypothesis testing method to use. Defaults to 'fisher1925' for the independent groups test and 'steiger1980' for overlap/non-overlap tests
gen_fun	function used to generate the required discrete data. Object returned must be a matrix with n rows. Default uses gen_2r . User defined version of this function must include the argument . . .
return_analysis	logical; return the analysis object for further extraction and customization?
. . .	additional arguments to be passed to gen_fun. Not used unless a customized gen_fun is defined
R	a correlation matrix constructed from the inputs to p_2r

Details

For independent group tests, only r.ab and r.ab2 need to be specified, where the null hypothesis pertains to $H_0 : r_{ab} = r_{ab2}$.

For overlapping correlation tests, r.ab, r.ac, and r.bc need to be specified, where the null hypothesis pertains to $H_0 : r_{ab} = r_{ac}$.

For non-overlapping correlation tests, all correlations expect for r.ab2 must be specified, where the null hypothesis pertains to $H_0 : r_{ab} = r_{cd}$.

Value

a single p-value

Author(s)

Phil Chalmers <rphilip.chalmers@gmail.com>

Examples

```
# independent (same x-y pairing across groups)
p_2r(100, r.ab=.5, r.ab2=.6)

# return cocor object for further analysis
p_2r(100, r.ab=.5, r.ab2=.6, return_analysis = TRUE)
```

```

# estimate empirical power
p_2r(n=100, r.ab=.5, r.ab2=.6) |> Spower()

# estimate n required to reach 80% power
p_2r(n=interval(100, 5000), r.ab=.5, r.ab2=.6) |> Spower(power=.80)

# overlap (same y, different xs)
# H0: r.ab = r.bc
p_2r(100, r.ab=.5, r.ac=.3, r.bc=.2)

# nonoverlap (different ys, different xs)
# H0: r.ab = r.cd
p_2r(100, r.ab=.5, r.ac=.3, r.bc=.2, r.ad=.2, r.bd=.4, r.cd=.2)

```

p_anova.test

p-value from one-way ANOVA simulation

Description

Generates continuous multi-sample data to be analyzed by a one-way ANOVA, and return a p-value. Uses the function [oneway.test](#) to perform the analyses. The data and associated test assume that the conditional observations are normally distributed and have equal variance by default, however these may be modified.

Usage

```

p_anova.test(
  n,
  k,
  f,
  n.ratios = rep(1, k),
  two.tailed = TRUE,
  var.equal = TRUE,
  means = NULL,
  sds = NULL,
  gen_fun = gen_anova.test,
  return_analysis = FALSE,
  ...
)

gen_anova.test(n, k, f, n.ratios = rep(1, k), means = NULL, sds = NULL, ...)

```

Arguments

n	sample size per group
k	number of groups
f	Cohen's f effect size
n.ratios	allocation ratios reflecting the sample size ratios. Default of 1 sets the groups to be the same size (n * n.ratio)
two.tailed	logical; should a two-tailed or one-tailed test be used?
var.equal	logical; use the pooled SE estimate instead of the Welch correction for unequal variances?
means	(optional) vector of means. When specified the input f is ignored
sds	(optional) vector of SDs. When specified the input f is ignored
gen_fun	function used to generate the required data. Object returned must be a matrix with k rows and k columns of numeric data. Default uses gen_anova.test . User defined version of this function must include the argument ...
return_analysis	logical; return the analysis object for further extraction and customization?
...	additional arguments to be passed to gen_fun. Not used unless a customized gen_fun is defined

Value

a single p-value

Author(s)

Phil Chalmers <rphilip.chalmers@gmail.com>

Examples

```
# n=50 in 3 groups, "medium" effect size
p_anova.test(50, k=3, f=.25)

# return analysis model
p_anova.test(50, k=3, f=.25, return_analysis=TRUE)

# explicit means/sds
p_anova.test(50, 3, means=c(0,0,1), sds=c(1,2,1))

# compare simulated results to pwr package
pwr::pwr.anova.test(f=0.28, k=4, n=20)
p_anova.test(n=20, k=4, f=.28) |> Spower()
```

p_chisq.test	<i>p-value from chi-squared test simulation</i>
--------------	---

Description

Generates multinomial data suitable for analysis with `chisq.test`.

Usage

```
p_chisq.test(  
  n,  
  w,  
  df,  
  correct = TRUE,  
  P0 = NULL,  
  P = NULL,  
  gen_fun = gen_chisq.test,  
  return_analysis = FALSE,  
  ...  
)  
  
gen_chisq.test(n, P, ...)
```

Arguments

n	sample size per group
w	Cohen's w effect size
df	degrees of freedom
correct	logical; apply continuity correction?
P0	specific null pattern, specified as a numeric vector or matrix
P	specific power configuration, specified as a numeric vector or matrix
gen_fun	function used to generate the required discrete data. Object returned must be a matrix with k rows and k columns of counts. Default uses <code>gen_chisq.test</code> . User defined version of this function must include the argument ...
return_analysis	logical; return the analysis object for further extraction and customization?
...	additional arguments to be passed to <code>gen_fun</code> . Not used unless a customized <code>gen_fun</code> is defined

Value

a single p-value

Author(s)

Phil Chalmers <rphilip.chalmers@gmail.com>

See Also[gen_chisq.test](#)**Examples**

```

# effect size w + df
p_chisq.test(100, w=.2, df=3)

# return analysis model
p_chisq.test(100, w=.2, df=3, return_analysis=TRUE)

# vector of explicit probabilities (goodness of fit test)
p_chisq.test(100, P0 = c(.25, .25, .25, .25),
             P = c(.6, .2, .1, .1))

# matrix of explicit probabilities (two-dimensional test of independence)
p_chisq.test(100, P0 = matrix(c(.25, .25, .25, .25), 2, 2),
             P = matrix(c(.6, .2, .1, .1), 2, 2))

# compare simulated results to pwr package

P0 <- c(1/3, 1/3, 1/3)
P <- c(.5, .25, .25)
w <- pwr::ES.w1(P0, P)
df <- 3-1
pwr::pwr.chisq.test(w=w, df=df, N=100, sig.level=0.05)

# slightly less power when evaluated empirically
p_chisq.test(n=100, w=w, df=df) |> Spower(replications=100000)

p_chisq.test(n=interval(1000, 2000), w=.1, df=df, correct=FALSE) |>
  Spower(power=.95)

```

Description

p-values associated with (generalized) linear regression model. Requires a pre-specified design matrix (X).

Usage

```
p_glm(
  formula,
  X,
  betas,
  test,
  sigma = NULL,
  family = gaussian(),
  gen_fun = gen_glm,
  return_analysis = FALSE,
  ...
)
```

```
gen_glm(formula, X, betas, sigma = NULL, family = gaussian(), ...)
```

Arguments

formula	formula passed to either <code>lm</code> or <code>glm</code>
X	a <code>data.frame</code> containing the covariates
betas	vector of slope coefficients that match the <code>model.matrix</code> version of X
test	character vector specifying the test to pass to <code>lht</code> . Can also be a list of character vectors to evaluate multiple tests
sigma	residual standard deviation for linear model. Only used when <code>family = 'gaussian'</code>
family	family of distributions to use (see <code>family</code>)
gen_fun	function used to generate the required discrete data. Object returned must be a <code>data.frame</code> . Default uses <code>gen_glm</code> . User defined version of this function must include the argument <code>...</code>
return_analysis	logical; return the analysis object for further extraction and customization?
...	additional arguments to be passed to <code>gen_fun</code> . Not used unless a customized <code>gen_fun</code> is defined

Value

a single p-value

Author(s)

Phil Chalmers <rphilip.chalmers@gmail.com>

See Also[p_lm.R2](#)**Examples**

```

X <- data.frame(G = factor(rep(c('control', 'treatment'), each=50)),
                C = sample(50:100, 100, replace=TRUE))
head(X)

# ANCOVA setup
p_glm(y ~ G + C, test="Gtreatment = 0",
      X=X, betas=c(10, .3, 1), sigma=1)

# return analysis model
p_glm(y ~ G + C, test="Gtreatment = 0",
      X=X, betas=c(10, .3, 1), sigma=1, return_analysis=TRUE)

# ANCOVA setup with logistic regression
p_glm(y ~ G + C, test="Gtreatment = 0",
      X=X, betas=c(-2, .5, .01), family=binomial())

# ANCOVA setup with poisson regression
p_glm(y ~ G + C, test="Gtreatment = 0",
      X=X, betas=c(-2, .5, .01), family=poisson())

# test whether two slopes differ given different samples.
# To do this setup data as an MLR where a binary variable S
# is used to reflect the second sample, and the interaction
# effect evaluates the magnitude of the slope difference
gen_twogroup <- function(n, dbeta, sdx1, sdx2, sigma, n2_n1 = 1, ...){
  X1 <- rnorm(n, sd=sdx1)
  X2 <- rnorm(n*n2_n1, sd=sdx2)
  X <- c(X1, X2)
  N <- length(X)
  S <- c(rep(0, n), rep(1, N-n))
  y <- dbeta * X*S + rnorm(N, sd=sigma)
  dat <- data.frame(y, X, S)
  dat
}

# prospective power using test that interaction effect is equal to 0
p_glm(formula=y~X*S, test="X:S = 0",
      n=100, sdx1=1, sdx2=2, dbeta=0.2,
      sigma=0.5, gen_fun=gen_twogroup) |> Spower(replications=1000)

```

p_kruskal.test	<i>p-value from Kruskal-Wallis Rank Sum Test simulation</i>
----------------	---

Description

Simulates data given two or more parent distributions and returns a p-value using `kruskal.test`. Default generates data from Gaussian distributions, however this can be modified.

Usage

```
p_kruskal.test(  
  n,  
  k,  
  means,  
  n.ratios = rep(1, k),  
  gen_fun = gen_kruskal.test,  
  return_analysis = FALSE,  
  ...  
)  
  
gen_kruskal.test(n, k, n.ratios, means, ...)
```

Arguments

n	sample size per group
k	number of groups
means	vector of means to control location parameters
n.ratios	allocation ratios reflecting the sample size ratios. Default of 1 sets the groups to be the same size (n * n.ratio)
gen_fun	function used to generate the required data. Object returned must be a list of length k, where each element contains the sample data in each group. Default uses <code>gen_kruskal.test</code> . User defined version of this function must include the argument ...
return_analysis	logical; return the analysis object for further extraction and customization?
...	additional arguments to pass to <code>gen_fun</code>

Value

a single p-value

Author(s)

Phil Chalmers <rphilip.chalmers@gmail.com>

Examples

```
# three group test where data generate from Gaussian distributions
p_ks.test(n=30, k=3, means=c(0, .5, .6))

# return analysis model
p_ks.test(n=30, k=3, means=c(0, .5, .6), return_analysis=TRUE)

# generate data from chi-squared distributions with different variances
gen_chisq <- function(n, k, n.ratios, means, dfs, ...){
  dat <- vector('list', k)
  ns <- n * n.ratios
  for(g in 1:k)
    dat[[g]] <- rchisq(ns[g], df=dfs[g]) - dfs[g] + means[g]
  dat
}

p_ks.test(n=30, k=3, means=c(0, 1, 2),
  gen_fun=gen_chisq, dfs=c(10, 15, 20))

# empirical power estimate
p_ks.test(n=30, k=3, means=c(0, .5, .6)) |> Spower()
p_ks.test(n=30, k=3, means=c(0, 1, 2), gen_fun=gen_chisq,
  dfs = c(10, 15, 20)) |> Spower()
```

p_ks.test

p-value from Kolmogorov-Smirnov one- or two-sample simulation

Description

Generates one or two sets of continuous data group-level data and returns a p-value under the null that the groups were drawn from the same distribution (two sample) or from a theoretically known distribution (one sample).

Usage

```
p_ks.test(
  n,
  p1,
  p2,
  n2_n1 = 1,
  two.tailed = TRUE,
  parent = NULL,
  return_analysis = FALSE,
  ...
)
```

Arguments

n	sample size per group, assumed equal across groups
p1	a function indicating how the data were generated for group 1
p2	(optional) a function indicating how the data were generated for group 2. If omitted a one-sample test will be evaluated provided that parent is also specified
n2_n1	sample size ratio. Default uses equal sample sizes
two.tailed	logical; should a two-tailed or one-tailed test be used?
parent	the cumulative distribution function to use (e.g., pnorm). Specifying this input will construct a one-sample test setup
return_analysis	logical; return the analysis object for further extraction and customization?
...	additional arguments to be passed to the parent distribution function from ks.test , as well as any other relevant parameter to ks.test (e.g., <code>exact = TRUE</code>)

Value

a single p-value

Author(s)

Phil Chalmers <rphilip.chalmers@gmail.com>

# empirical power estimates
p_ks.test(n=100, p1, p2) |> Spower()
p_ks.test(n=100, p1=pc, parent=pnorm, mean=0, sd=1) |> Spower()
```

p_lm.R2

p-value from global linear regression model simulation

Description

p-values associated with linear regression model using fixed/random independent variables. Focus is on the omnibus behavior of the R^2 statistic.

Usage

```
p_lm.R2(
  n,
  R2,
  k,
  R2_0 = 0,
  k.R2_0 = 0,
  R2.resid = 1 - R2,
  fixed = TRUE,
  return_analysis = FALSE,
  ...
)
```

Arguments

n	sample size
R2	R-squared effect size
k	number of IVs
R2_0	null hypothesis for R-squared
k.R2_0	number of IVs associated with the null hypothesis model
R2.resid	residual R-squared value, typically used when comparing nested models when fit sequentially (e.g., comparing model A vs B when model involves the structure A -> B -> C)
fixed	logical; if FALSE then the data are random generated according to a joint multivariate normal distribution
return_analysis	logical; return the analysis object for further extraction and customization?
...	additional arguments to be passed to gen_fun. Not used unless a customized gen_fun is defined

Value

a single p-value

Author(s)

Phil Chalmers <rphilip.chalmers@gmail.com>

# return analysis model
p_lm.R2(n=95, R2=.1, k=5, return_analysis=TRUE)
```

p_mauchly.test	<i>p-value from Mauchly's Test of Sphericity simulation</i>
----------------	---

Description

Perform simulation experiment for Mauchly's Test of Sphericity using the function `mauchlys.test`, returning a p-value. Assumes the data are from a multivariate normal distribution, however this can be modified.

Usage

```
p_mauchly.test(
  n,
  sigma,
  gen_fun = gen_mauchly.test,
  return_analysis = FALSE,
  ...
)

gen_mauchly.test(n, sigma, ...)

mauchlys.test(X)
```

Arguments

n	sample size
sigma	symmetric covariance/correlation matrix passed to <code>gen_fun</code>

gen_fun function used to generate the required data. Object returned must be a matrix with K columns and n rows. Default uses `gen_mauchly.test` to generate multivariate normal samples. User defined version of this function must include the argument ...
return_analysis logical; return the analysis object for further extraction and customization?
... additional arguments to be passed to `gen_fun`. Not used unless a customized `gen_fun` is defined
X a matrix with k columns and n rows

Value

a single p-value

Author(s)

Phil Chalmers <rphilip.chalmers@gmail.com>

Examples

```

sigma <- diag(c(1,2,1))
sigma

# H0 test that sphericity holds
p_mauchly.test(100, sigma=sigma)

# return analysis object
p_mauchly.test(100, sigma=sigma, return_analysis=TRUE)

# Null is true
sigma.H0 <- diag(3)
p_mauchly.test(100, sigma=sigma.H0)

# empirical power estimate
p_mauchly.test(100, sigma=sigma) |> Spower()

# empirical Type I error estimate
p_mauchly.test(100, sigma=sigma.H0) |> Spower()

```

`p_mcnemar.test`

p-value from McNemar test simulation

Description

Generates two-dimensional sample data for McNemar test and return a p-value. Uses `mcnemar.test`.

Usage

```
p_mcnemar.test(
  n,
  prop,
  OR = NULL,
  prop.disc = NULL,
  two.tailed = TRUE,
  correct = TRUE,
  gen_fun = gen_mcnemar.test,
  return_analysis = FALSE,
  ...
)

gen_mcnemar.test(n, prop, ...)
```

Arguments

n	total sample size
prop	two-dimensional matrix of proportions/probabilities
OR	instead of supplying the prop table, the odds ratio can be specified instead π_{12}/π_{21} . Also requires proportion of discordant pairings to be specified
prop.disc	proportion of discordant pairings, $\pi_{12} + \pi_{21}$
two.tailed	logical; should a two-tailed or one-tailed test be used?
correct	logical; use continuity correction? Only applicable for 2x2 tables
gen_fun	function used to generate the required discrete data. Object returned must be a matrix with k rows and k columns of counts. Default uses gen_mcnemar.test . User defined version of this function must include the argument ...
return_analysis	logical; return the analysis object for further extraction and customization?
...	additional arguments to be passed to gen_fun. Not used unless a customized gen_fun is defined

Value

a single p-value

Author(s)

Phil Chalmers <rphilip.chalmers@gmail.com>

  Spower(replications=30000)

```

p_mediation

p-value from three-variable mediation analysis simulation

Description

Simple 3-variable mediation analysis simulation to test the hypothesis that $X \rightarrow Y$ is mediated by the relationship $X \rightarrow M \rightarrow Y$. Currently, M and Y are assumed to be continuous variables with Gaussian errors, while X may be continuous or dichotomous.

Usage

```

p_mediation(
  n,
  a,
  b,
  cprime,
  dichotomous.X = FALSE,
  two.tailed = TRUE,
  method = "wald",
  sd.X = 1,
  sd.Y = 1,

```

```

    sd.M = 1,
    gen_fun = gen_mediation,
    return_analysis = FALSE,
    ...
)

gen_mediation(
  n,
  a,
  b,
  cprime,
  dichotomous.X = FALSE,
  sd.X = 1,
  sd.Y = 1,
  sd.M = 1,
  ...
)

```

Arguments

n	total sample size unless dichotomous.X = TRUE, in which the value represents the size per group
a	regression coefficient for the path X -> M
b	regression coefficient for the path M -> Y
cp	partial regression coefficient for the path X -> Y
dichotomous.X	logical; should the X variable be generated as though it were dichotomous? If TRUE then n represents the sample size per group
two.tailed	logical; should a two-tailed or one-tailed test be used?
method	type of inferential method to use. Default uses the Wald (a.k.a., Sobel) test
sd.X	standard deviation for X
sd.Y	standard deviation for Y
sd.M	standard deviation for M
gen_fun	function used to generate the required two-sample data. Object returned must be a data.frame with the columns "DV" and "group". Default uses gen_mediation to generate conditionally Gaussian distributed samples. User defined version of this function must include the argument ...
return_analysis	logical; return the analysis object for further extraction and customization?
...	additional arguments to be passed to gen_fun. Not used unless a customized gen_fun is defined

Value

a single p-value

Author(s)

Examples

```
# joint test H0: a*b = 0
p_mediation(50, a=sqrt(.35), b=sqrt(.35), cprime=.39)
p_mediation(50, a=sqrt(.35), b=sqrt(.35), cprime=.39, dichotomous.X=TRUE)

# return analysis model
p_mediation(50, a=sqrt(.35), b=sqrt(.35), cprime=.39, return_analysis=TRUE)

# data generation properties
N <- 1000
dat <- gen_mediation(n = N, a = .8, b = -.7, cprime = .2,
  sd.X = 2, sd.Y = 3, sd.M = 2)
descript(dat) # specific SDs

# two-step regression-based estimates (not used)
lm(M ~ X, data=dat) |> coef()      # a
lm(Y ~ M + X, data=dat) |> coef() # b and cprime
lm(Y ~ X, data=dat) |> coef()     # c = cprime + a*b

# same properties, but dichotomous X variable
dat <- gen_mediation(n = N, a = .8, b = -.7, cprime = .2,
  sd.X = 2, sd.Y = 3, sd.M = 2, dichotomous.X = TRUE)
descript(dat) # specific SDs

# two-step regression-based estimates (not used)
lm(M ~ X, data=dat) |> coef()      # a
lm(Y ~ M + X, data=dat) |> coef() # b and cprime
lm(Y ~ X, data=dat) |> coef()     # c = cprime + a*b

# power to detect mediation
p_mediation(n=50, a=sqrt(.35), b=sqrt(.35), cprime=.39) |>
  Spower(parallel=TRUE, replications=1000)

# sample size estimate for .95 power
p_mediation(n=interval(50,200), a=sqrt(.35), b=sqrt(.35), cprime=.39) |>
  Spower(power=.95, parallel=TRUE)
```

p_prop.test *p-value from proportion test simulation*

Description

Generates single and multi-sample data for proportion tests and return a p-value. Uses `binom.test` for one-sample applications and `prop.test` otherwise.

Usage

```
p_prop.test(
  n,
  h,
  prop = NULL,
  pi = 0.5,
  n.ratios = rep(1, length(prop)),
  two.tailed = TRUE,
  correct = TRUE,
  exact = FALSE,
  gen_fun = gen_prop.test,
  return_analysis = FALSE,
  ...
)

gen_prop.test(
  n,
  h,
  prop = NULL,
  pi = 0.5,
  n.ratios = rep(1, length(prop)),
  ...
)
```

Arguments

n	sample size per group
h	Cohen's h effect size; only supported for one-sample analysis. Note that it's important to specify the null value pi when supplying this effect size as the power changes depending on these specific values (see example below).
prop	sample probability/proportions of success. If a vector with two-values or more elements are supplied then a multi-samples test will be used. Matrices are also supported
pi	probability of success to test against (default is .5). Ignored for two-sample tests
n.ratios	allocation ratios reflecting the sample size ratios. Default of 1 sets the groups to be the same size (n * n.ratio)

<code>two.tailed</code>	logical; should a two-tailed or one-tailed test be used?
<code>correct</code>	logical; use Yates' continuity correction?
<code>exact</code>	logical; use fisher's exact test via <code>fisher.test</code> ? Use of this flag requires that <code>prop</code> was specified as a matrix
<code>gen_fun</code>	function used to generate the required discrete data. Object returned must be a matrix with two rows and 1 or more columns. Default uses <code>gen_prop.test</code> . User defined version of this function must include the argument ...
<code>return_analysis</code>	logical; return the analysis object for further extraction and customization?
...	additional arguments to be passed to <code>gen_fun</code> . Not used unless a customized <code>gen_fun</code> is defined

Value

a single p-value

  Spower()

# three-sample joint test, equal n's
p_prop.test(n=50, prop=c(.6,.4,.7)) |> Spower()

```

p_r

p-value from correlation simulation

Description

Generates correlated X-Y data and returns a p-value to assess the null of no correlation in the population. The X-Y data are generated assuming a bivariate normal distribution.

Usage

```

p_r(
  n,
  r,
  rho = 0,
  method = "pearson",
  two.tailed = TRUE,
  gen_fun = gen_r,
  return_analysis = FALSE,
  ...

```

```
)
gen_r(n, r, means = c(0, 0), ...)
```

Arguments

n	sample size
r	correlation
rho	population coefficient to test against. Uses the Fisher's z-transformation approximation when non-zero
method	method to use to compute the correlation (see cor.test). Only used when rho = 0
two.tailed	logical; should a two-tailed or one-tailed test be used?
gen_fun	function used to generate the required dependent bivariate data. Object returned must be a <code>matrix</code> with two columns and n rows. Default uses gen_r to generate conditionally dependent data from a bivariate normal distribution. User defined version of this function must include the argument ...
return_analysis	logical; return the analysis object for further extraction and customization? Note that if rho != 0 the p.value and related element will be replaced with internally computed approximation versions
...	additional arguments to be passed to gen_fun. Not used unless a customized gen_fun is defined
means	mean vector for data generation, of length 2. Defaults to c(0, 0)

Value

a single p-value

Author(s)

Phil Chalmers <rphilip.chalmers@gmail.com>

p_r(n=interval(200, 1000), r=0.1) |> Spower(power=.80)

```

p_r.cat

p-value from tetrachoric/polychoric or polyserial

Description

Generates correlated X-Y data and returns a p-value to assess the null of no correlation in the population. The X-Y data are generated assuming a multivariate normal distribution and subsequently discretized for one or both of the variables.

Usage

```

p_r.cat(
  n,
  r,
  tauX,
  rho = 0,
  tauY = NULL,
  ML = TRUE,
  two.tailed = TRUE,
  score = FALSE,
  gen_fun = gen_r,
  return_analysis = FALSE,
  ...
)

```

Arguments

n	sample size
r	correlation prior to the discretization (recovered via the polyserial/polychoric estimates)
tauX	intercept parameters used for discretizing the X variable

rho	population coefficient to test against
tauY	intercept parameters used for discretizing the Y variable. If missing a polyserial correlation will be estimated, otherwise a tetrachoric/polychoric correlation will be estimated
ML	logical; use maximum-likelihood estimation?
two.tailed	logical; should a two-tailed or one-tailed test be used?
score	logical; should the SE be based at the null hypothesis (score test) or the ML estimate (Wald test)? The former is the canonical form for a priori power analyses though requires twice as many computations as the Wald test approach
gen_fun	function used to generate the required continuous bivariate data (prior to truncation). Object returned must be a <code>matrix</code> with two columns. Default uses <code>gen_r</code> to generate conditionally dependent data from a bivariate normal distribution. User defined version of this function must include the argument <code>...</code>
return_analysis	logical; return the analysis object for further extraction and customization?
...	additional arguments to be passed to <code>gen_fun</code> . Not used unless a customized <code>gen_fun</code> is defined

Value

a single p-value

Author(s)

Phil Chalmers <rphilip.chalmers@gmail.com>

Examples

```
# 100 observations, .5 correlation, tetrachoric estimate
p_r.cat(100, r=.5, tauX=0, tauY=1)

# return analysis model
p_r.cat(100, r=.5, tauX=0, tauY=1, return_analysis=TRUE)

# Wald test
p_r.cat(100, r=.5, tauX=0, tauY=1, score=FALSE)

# polyserial estimate (Y continuous)
p_r.cat(50, r=.5, tauX=0)
```

p_scale	<i>p-value from Scale Test simulation</i>
---------	---

Description

Simulates data given one or two parent distributions and returns a p-value testing that the scale of the type distributions are the same. Default implementation uses Gaussian distributions, however the distribution function may be modified to reflect other populations of interest. Uses [ansari.test](#) or [mood.test](#) for the analysis.

Usage

```
p_scale(  
  n,  
  scale,  
  n2_n1 = 1,  
  two.tailed = TRUE,  
  exact = NULL,  
  test = "Ansari",  
  parent = function(n, ...) rnorm(n),  
  ...,  
  return_analysis = FALSE  
)
```

Arguments

n	sample size per group
scale	the scale to multiply the second group by (1 reflects equal scaling)
n2_n1	sample size ratio
two.tailed	logical; use two-tailed test?
exact	a logical indicating whether an exact p-value should be computed
test	type of method to use. Can be either 'Ansari' or 'Mood'
parent	data generation function (default assumes Gaussian shape). Must be population mean centered
...	additional arguments to pass to simulation functions (if used)
return_analysis	logical; return the analysis object for further extraction and customization?

Value

a single p-value

Author(s)

Phil Chalmers <rphilip.chalmers@gmail.com>

Examples

```
# n=30 per group,
# Distributions Gaussian with sd=1 for first group and sd=2 for second
p_scale(30, scale=2)
p_scale(30, scale=2, test='Mood')

# compare chi-squared distributions
parent <- function(n, df, ...) rchisq(n, df=df) - df
p_scale(30, scale=2, parent=parent, df=3)

# empirical power of the experiments
p_scale(30, scale=2) |> Spower()
p_scale(30, scale=2, test='Mood') |> Spower()

p_scale(30, scale=2, parent=parent, df=3) |> Spower()
p_scale(30, scale=2, test='Mood', parent=parent, df=3) |> Spower()
```

p_shapiro.test

p-value from Shapiro-Wilk Normality Test simulation

Description

Generates univariate distributional data and returns a p-value to assess the null that the population follows a Gaussian distribution shape. Uses [shapiro.test](#).

Usage

```
p_shapiro.test(dist, return_analysis = FALSE)
```

Arguments

`dist` expression used to generate the required sample data
`return_analysis` logical; return the analysis object for further extraction and customization?

Value

a single p-value

Author(s)

Phil Chalmers <rphilip.chalmers@gmail.com>

Examples

```
# 50 observations drawn from normal distribution (null is true)
p_shapiro.test(rnorm(50))

# return analysis object
p_shapiro.test(rnorm(50), TRUE)

# 50 observations from slightly skewed chi-squared distribution (power)
p_shapiro.test(rchisq(50, df=100))

# empirical Type I error rate estimate
p_shapiro.test(rnorm(50)) |> Spower()

# power
p_shapiro.test(rchisq(50, df=100)) |> Spower()
```

p_slr

p-value from simple linear regression model simulation

Description

p-values associated with the simple linear regression model, $y = \beta_0 + \beta_1 X + \epsilon$. Focus is on the slope/intercept behavior of the model.

Usage

```
p_slr(
  n,
  beta,
  sd_x,
  sd_y,
  beta0 = 0,
  test = "x = 0",
  gen_fun = gen_slr,
  return_analysis = FALSE,
  ...
)

gen_slr(n, beta, sd_x, sd_y, ...)
```

Arguments

n	sample size
beta	slope parameter

sd_x	standard deviation of IV
sd_y	standard deviation of DV
beta0	null value to test against
test	test to evaluate using lht . Default evaluates the null hypothesis that the slope is equal to 0
gen_fun	function used to generate the required X-Y data. Object returned must be a <code>data.frame</code> with the columns 'y' and 'x'. Default uses gen_slr . User defined version of this function must include the argument ...
return_analysis	logical; return the analysis object for further extraction and customization?
...	additional arguments to be passed to <code>gen_fun</code> . Not used unless a customized <code>gen_fun</code> is defined

Value

a single p-value

Author(s)

Phil Chalmers <rphilip.chalmers@gmail.com>

See Also

[p_glm](#), [p_lm.R2](#)

Examples

```
p_slr(n=100, beta = -0.0667, sd_x = 7.5, sd_y = 4)

## Not run:
p_slr(n=100, beta = -0.0667, sd_x = 7.5, sd_y = 4) |> Spower()

## End(Not run)
```

p_t.test

p-value from independent/paired samples t-test simulation

Description

Generates one or two sets of continuous data group-level data according to Cohen's effect size 'd', and returns a p-value. The data and associated t-test assume that the conditional observations are normally distributed and have equal variance by default, however these may be modified.

Usage

```

p_t.test(
  n,
  d,
  mu = 0,
  r = NULL,
  type = "two.sample",
  n2_n1 = 1,
  two.tailed = TRUE,
  var.equal = TRUE,
  means = NULL,
  sds = NULL,
  conf.level = 0.95,
  gen_fun = gen_t.test,
  return_analysis = FALSE,
  ...
)

gen_t.test(
  n,
  d,
  n2_n1 = 1,
  r = NULL,
  type = "two.sample",
  means = NULL,
  sds = NULL,
  ...
)

```

Arguments

n	sample size per group, assumed equal across groups. For paired samples this corresponds to the number of pairs (hence, half the number of data points observed)
d	Cohen's standardized effect size d. For the generated data this standardized mean appears in the first group (two-sample)/first time point (paired samples)
mu	population mean to test against
r	(optional) instead of specifying d specify a point-biserial correlation. Internally this is transformed into a suitable d value for the power computations
type	type of t-test to use; can be 'two.sample', 'one.sample', or 'paired'
n2_n1	allocation ratio reflecting the same size ratio. Default of 1 sets the groups to be the same size. Only applicable when type = 'two.sample'
two.tailed	logical; should a two-tailed or one-tailed test be used?
var.equal	logical; use the classical or Welch corrected t-test?
means	(optional) vector of means for each group. When specified the input d is ignored

sds	(optional) vector of SDs for each group. If not specified and d is used then these are set to a vector of 1's
conf.level	confidence interval level passed to <code>t.test</code>
gen_fun	function used to generate the required two-sample data. Object returned must be a list containing one (one-sample) or two (independent samples/paired samples) elements, both of which are numeric vectors. Default uses <code>gen_t.test</code> to generate conditionally Gaussian distributed samples. User defined version of this function must include the argument ...
return_analysis	logical; return the analysis object for further extraction and customization?
...	additional arguments to be passed to <code>gen_fun</code> . Not used unless a customized <code>gen_fun</code> is defined

Value

a single p-value

Author(s)

Phil Chalmers <rphilip.chalmers@gmail.com>

  Spower(replications=30000)

```

p_var.test

p-value from variance test simulation

Description

Generates one or more sets of continuous data group-level data to perform a variance test, and return a p-value. When two-samples are investigated the `var.test` function will be used, otherwise functions from the EnvStats package will be used.

Usage

```
p_var.test(
  n,
  vars,
  n.ratios = rep(1, length(vars)),
  sigma2 = 1,
  two.tailed = TRUE,
  test = "Levene",
  correct = TRUE,
  gen_fun = gen_var.test,
  return_analysis = FALSE,
  ...
)
```

```
gen_var.test(n, vars, n.ratios = rep(1, length(vars)), ...)
```

Arguments

n	sample size per group, assumed equal across groups
vars	a vector of variances to use for each group; length of 1 for one-sample tests
n.ratios	allocation ratios reflecting the sample size ratios. Default of 1 sets the groups to be the same size ($n * n.ratio$)
sigma2	population variance to test against in one-sample test
two.tailed	logical; should a two-tailed or one-tailed test be used?
test	type of test to use in multi-sample applications. Can be either 'Levene' (default), 'Bartlett', or 'Fligner'
correct	logical; use correction when test = 'Bartlett'?
gen_fun	function used to generate the required discrete data. Object returned must be a matrix with k rows and k columns of counts. Default uses <code>gen_var.test</code> . User defined version of this function must include the argument ...

```

return_analysis
    logical; return the analysis object for further extraction and customization?
...
    additional arguments to be passed to gen_fun. Not used unless a customized
    gen_fun is defined

```

Value

a single p-value

Author(s)

Phil Chalmers <rphilip.chalmers@gmail.com>

# three sample
p_var.test(100, vars=c(10, 9, 11))
p_var.test(100, vars=c(10, 9, 11), test = 'Fligner')
p_var.test(100, vars=c(10, 9, 11), test = 'Bartlett')

# power to detect three-group variance differences
p_var.test(n=100, vars=c(10,9,11)) |> Spower()

# sample size per group to achieve 80% power
p_var.test(n=interval(100, 2000), vars=c(10,9,11)) |> Spower(power=.80)

```

p_wilcox.test

p-value from Wilcoxon (signed rank) test simulation

Description

Simulates data given one (Wilcoxon) or two (Mann-Whitney) parent distributions and returns a p-value. Can also be used for power analyses related to sign tests.

Usage

```
p_wilcox.test(
  n,
  d,
  n2_n1 = 1,
  mu = 0,
  type = c("two.sample", "one.sample", "paired"),
  exact = NULL,
  correct = TRUE,
  two.tailed = TRUE,
  parent1 = function(n, d) rnorm(n, d, 1),
  parent2 = function(n, d) rnorm(n, 0, 1),
  return_analysis = FALSE
)
```

Arguments

<code>n</code>	sample size per group. For paired samples this corresponds to the number of pairings (hence, half of the data points observed)
<code>d</code>	effect size passed to parent functions
<code>n2_n1</code>	sample size ratio
<code>mu</code>	parameter used to form the null hypothesis
<code>type</code>	type of analysis to use (two-sample, one-sample, or paired)
<code>exact</code>	a logical indicating whether an exact p-value should be computed
<code>correct</code>	a logical indicating whether to apply continuity correction in the normal approximation for the p-value
<code>two.tailed</code>	logical; use two-tailed test?
<code>parent1</code>	data generation function for first group. Ideally should have SDs = 1 so that d reflects a standardized difference
<code>parent2</code>	same as parent1, but for the second group
<code>return_analysis</code>	logical; return the analysis object for further extraction and customization?

Value

a single p-value

Author(s)

Phil Chalmers <rphilip.chalmers@gmail.com>

Examples

```
# with normal distributions defaults d is standardized
p_wilcox.test(100, .5)
p_wilcox.test(100, .5, type = 'paired') # n = number of pairs
```

```

p_wilcox.test(100, .5, type = 'one.sample')

# return analysis object
p_wilcox.test(100, .5, return_analysis = TRUE)

# using chi-squared distributions (standardizing to 0-1)
p_wilcox.test(100, .5, type = 'one.sample',
  parent1 = function(n, d) rchisq(n, df=10) - 10 + d)
p_wilcox.test(100, .5,
  parent1 = function(n, d) (rchisq(n, df=10) - 10)/sqrt(20) + d,
  parent2 = function(n, d) (rchisq(n, df=10) - 10)/sqrt(20))

```

 Spower

Simulation-based Power Analyses

Description

General purpose function that provides power-focused estimates for a priori, prospective/post-hoc, compromise, sensitivity, and criterion power analysis. Function provides a general wrapper to the `SimDesign` package's `runSimulation` and `SimSolve` functions. As such, parallel processing is automatically supported, along with progress bars, (predicted) confidence intervals for the results estimates, safety checks, and more.

The function `SpowerBatch`, on the other hand, can be used to run `Spower` across different simulation combinations, returning a list of results instead. Can also be used as a pre-computing step before using `SpowerCurve`, and shares the same syntax specification (see `SpowerCurve` for further examples).

`SpowerCurve` draws power curves that either a) estimate the power given a set of varying conditions or b) solves a set of root conditions given fixed values of power. Confidence/predicted confidence intervals are included in the output to reflect the estimate uncertainties, though note that fewer replications/iterations are used compared to `Spower` as the goal is visualization of competing variable inputs rather than precision of a given input.

Usage

```

Spower(
  ...,
  power = NA,
  sig.level = 0.05,
  interval,
  beta_alpha,
  sig.direction = "below",
  replications = 10000,
  integer,
  parallel = FALSE,
  cl = NULL,
  packages = NULL,

```

```
ncores = parallelly::availableCores(omit = 1L),
predCI = 0.95,
predCI.tol = 0.01,
verbose = interactive(),
check.interval = FALSE,
maxiter = 150,
wait.time = NULL,
lastSpower = NULL,
select = NULL,
control = list()
)
```

```
## S3 method for class 'Spower'
print(x, ...)
```

```
## S3 method for class 'Spower'
as.data.frame(x, ...)
```

```
SpowerBatch(
  ...,
  interval = NULL,
  power = NA,
  sig.level = 0.05,
  beta_alpha = NULL,
  sig.direction = "below",
  replications = 10000,
  integer,
  fully.crossed = TRUE,
  parallel = FALSE,
  cl = NULL,
  ncores = parallelly::availableCores(omit = 1L),
  predCI = 0.95,
  predCI.tol = 0.01,
  verbose = interactive(),
  check.interval = FALSE,
  maxiter = 150,
  wait.time = NULL,
  select = NULL,
  control = list()
)
```

```
## S3 method for class 'SpowerBatch'
print(x, ...)
```

```
## S3 method for class 'SpowerBatch'
as.data.frame(x, ...)
```

```
SpowerCurve(
```

```

    ...,
    interval = NULL,
    power = NA,
    sig.level = 0.05,
    sig.direction = "below",
    replications = 2500,
    integer,
    plotCI = TRUE,
    plotly = TRUE,
    parallel = FALSE,
    cl = NULL,
    ncores = parallelly::availableCores(omit = 1L),
    predCI = 0.95,
    predCI.tol = 0.01,
    verbose = interactive(),
    check.interval = FALSE,
    maxiter = 50,
    wait.time = NULL,
    select = NULL,
    batch = NULL,
    control = list()
)

interval(lower, upper, integer, check.interval = FALSE)

```

Arguments

... expression to use in the simulation that returns a numeric vector containing either the p-value (under the null hypothesis), the probability of the alternative hypothesis in the Bayesian setting, where the first numeric value in this vector is treated as the focus for all analyses other than prospective/post-hoc power. This corresponds to the alpha value used to flag samples as 'significant' when evaluating the null hypothesis (via p-values; $P(D|H_0)$), where any returned p-value less than `sig.level` indicates significance. However, if `sig.direction = 'above'` then only values above `sig.level` are flagged as significant, which is useful in Bayesian posterior probability contexts that focus on the alternative hypothesis, $P(H_1|D)$.

Alternatively, a logical vector can be returned (e.g., when using confidence intervals (CIs) or evaluating regions of practical equivalence (ROPEs)), where the average of these TRUE/FALSE vector corresponds to the empirical power.

Finally, a named list or data frame can be returned instead if there is need for more general, heterogeneous objects, however a specific element to extract must be specified using the `select` argument to indicate which of the list elements are to be used in the power computations. All other elements from the simulation can, however, be extracted from the `SimResults` function.

For `SpowerCurve` and `SpowerBatch`, first expression input must be identical to ... in `Spower`, while the remaining named inputs must match the arguments to this expression to indicate which variables should be modified in the resulting

power curves. Providing NA values is also supported to solve the missing component. Note that only the first three named arguments in `SpowerCurve` will be plotted using the x-y, colour, and facet wrap aesthetics, respectively. However, if necessary the data can be extracted for further visualizations via `ggplot_build` to provide more customized control

power	power level to use. If set to NA (default) then the empirical power will be estimated given the fixed . . . inputs (e.g., for prospective/post-hoc power analysis). For <code>SpowerCurve</code> and <code>SpowerBatch</code> this can be a vector
sig.level	alpha level to use (default is .05). If set to NA then the value will be estimated given the fixed conditions input (e.g., for criterion power analysis). Only used when the value returned from the experiment is a numeric (e.g., a p-value, or a posterior probability; see <code>sig.direction</code>). If the return of the supplied experiment is a logical then this argument will be entirely ignored. As such, arguments such as <code>conf.level</code> should be included in the simulation experiment definition itself to indicate the explicit inferential criteria, and so that this argument can be manipulated should the need arise.
interval	required search interval to use when <code>SimSolve</code> is called to perform stochastic root solving. Note that for compromise analyses, where the <code>sig.level</code> is set to NA, if not set explicitly then the interval will default to <code>c(0, 1)</code> . Alternatively, though only for the function <code>Spower()</code> , the function <code>interval</code> can be used within the experiment function definition where the canonical NA placeholder is used. Arguments from <code>interval</code> will then be extracted and passed to <code>Spower</code> as usual. Note that this is not supported in <code>SpowerBatch</code> and <code>SpowerCurve</code> as multiple interval definitions are often required; hence, NA placeholders are always required in these wrapper functions
beta_alpha	(optional) ratio to use in compromise analyses corresponding to the Type II errors (beta) over the Type I error (alpha). Ratios greater than $q = \beta/\alpha = 1$ indicate that Type I errors are worse than Type II, while ratios less than one the opposite. A ratio equal to 1 gives an equal trade-off between Type I and Type II errors
sig.direction	a character vector that is either 'below' (default) or 'above' to indicate which direction relative to <code>sig.level</code> is considered significant. This is useful, for instance, when forming cutoffs for Bayesian posterior probabilities organized to show support for the hypothesis of interest ($P(H_1 D)$). As an example, setting <code>sig.level = .95</code> with <code>sig.direction = 'above'</code> flags a sample as 'significant' whenever the posterior probability is greater than .95.
replications	number of replications to use when <code>runSimulation</code> is required. Default is 10000, though set to 2500 for <code>SpowerCurve</code>
integer	a logical value indicating whether the search iterations use integers or doubles. If missing, automatically set to FALSE if <code>interval</code> contains non-integer numbers or the range is less than 5, as well as when <code>sig.level = NA</code>
parallel	for parallel computing for slower simulation experiments, defined using the <code>mirai</code> package by default (see <code>runSimulation</code> for details).
cl	see <code>runSimulation</code>
packages	see <code>runSimulation</code>

ncores	see runSimulation
predCI	predicting confidence interval level (see SimSolve)
predCI.tol	predicting confidence interval consistency tolerance for stochastic root solver convergence (see SimSolve). Default converges when the power rate CI is consistently within $.01/2$ of the target power
verbose	logical; should information be printed to the console? By default this is determined based on whether the session is interactive or not
check.interval	logical; check the interval range validity (see SimSolve). Disabled by default
maxiter	maximum number of stochastic root-solving iterations. Default is 150, though set to 50 for SpowerCurve
wait.time	(optional) argument to indicate the time to wait (specified in minutes if supplied as a numeric vector). See SimSolve for details and See timeFormatter for further specifications
lastSpower	a previously returned Spower object to be updated. Use this if you want to continue where an estimate left off but wish to increase the precision (e.g., by adding more replications, or by letting the stochastic root solver continue searching). Note that if the object was not stored use getLastSpower to obtain the last estimated power object
select	a character vector indicating which elements to extract from the provided stimulation experiment function. By default, all elements from the provided function will be used, however if the provided function contains information not relevant to the power computations (e.g., parameter estimates, standard errors, etc) then these should be ignored. To extract the complete results post-analysis use SimResults to allow manual summarizing of the stored results (applicable only with prospective/post-hoc power)
control	a list of control parameters to pass to runSimulation or SimSolve
x	object of class 'Spower'. If SpowerBatch were used the this will be a list
fully.crossed	logical; should the supplied conditions to SpowerBatch be fully crossed? Passed to the same argument documented in createDesign
plotCI	logical; include confidence/predicted confidence intervals in plots?
plotly	logical; draw the graphic into the interactive plotly interface? If FALSE the ggplot2 object will be returned instead
batch	if SpowerBatch were previously used to perform the computations then this information can be provided to this batch argument to avoid recomputing
lower	lower bound for stochastic search interval. If input contains a decimal then <code>Spower(..., integer)</code> will be set to FALSE
upper	upper bound for stochastic search interval. If input contains a decimal then <code>Spower(..., integer)</code> will be set to FALSE

Details

Five types of power analysis flavors can be performed with Spower, which are triggered based on which supplied input is set to missing (NA):

A Priori Solve for a missing sample size component (e.g., n) to achieve a specific target power rate

Prospective and Post-hoc Estimate the power rate given a set of fixed conditions. If estimates of effect sizes and other empirical characteristics (e.g., observed sample size) are supplied this results in observed/retrospective power (not recommended), while if only sample size is included as the observed quantity, but the effect sizes are treated as unknown, then this results in post-hoc power (Cohen, 1988)

Sensitivity Solve a missing effect size value as a function of the other supplied constant components

Criterion Solve the error rate (argument `sig.level`) as a function of the other supplied constant components

Compromise Solve a Type I/Type II error trade-off ratio as a function of the other supplied constant components and the target ratio $q = \beta/\alpha$ (argument `beta_alpha`)

To understand how the package is structured, the first expression in the `...` argument, which contains the simulation experiment definition for a single sample, is passed to either `SimSolve` or `runSimulation` depending on which element (including the power and `sig.level` arguments) is set to `NA`. For instance, `Spower(p_t.test(n=50, d=.5))` will perform a prospective/post-hoc power evaluation since `power = NA` by default, while `Spower(p_t.test(n=NA, d=.5), power = .80)` or, equivalently, `Spower(p_t.test(n=interval(. , .), d=.5), power = .80)`, will perform an a priori power analysis to solve the missing `n` argument.

For expected power computations, the arguments to the simulation experiment arguments can be specified as a function to reflect the prior uncertainty. For instance, if `d_prior <- function() rnorm(1, mean=.5, sd=1/8)` then `Spower(p_t.test(n=50, d=d_prior())` will compute the expected power over the prior sampling distribution for `d`

Value

an invisible tibble/data.frame-type object of class 'Spower' containing the power results from the simulation experiment

a ggplot2 object automatically rendered with plotly for interactivity

nbatch
as.data.frame(nbatch)

# plot the results, but avoid further computations
SpoverCurve(batch=nbatch)

```

update.Spover	<i>Update compromise or prospective/post-hoc power analysis without re-simulating</i>
---------------	---

Description

When a power or compromise analysis was performed in [Spover](#) this function can be used to update the compromise or power criteria without the need for re-simulating the experiment. For compromise analyses a beta_alpha criteria must be supplied, while for prospective/post-hoc power analyses the sig.level must be supplied.

Usage

```

## S3 method for class 'Spover'
update(object, sig.level = 0.05, beta_alpha = NULL, predCI = 0.95, ...)

```

Arguments

object	object returned from Spover where power was estimated or the beta_alpha criteria were supplied
sig.level	Type I error rate (alpha)
beta_alpha	Type II/Type I error ratio
predCI	confidence interval precision (see Spover for similar input)
...	arguments to be passed

Value

object of class Spover with updated information

Author(s)

Phil Chalmers <rphilip.chalmers@gmail.com>

Examples

```
#####  
## Prospective power analysis update  
  
# Estimate power using sig.level = .05 (default)  
out <- p_t.test(n = 50, d = .5) |> Spover()  
  
# update power estimate given sig.level=.01 and .20  
update(out, sig.level=.01)  
update(out, sig.level=.20)  
  
#####  
## Compromise analysis update  
  
# Solve beta/alpha ratio to specific error trade-off constant  
out <- p_t.test(n = 50, d = .5) |> Spover(beta_alpha = 2)  
  
# update beta_alpha criteria without re-simulating  
update(out, beta_alpha=4)  
  
# also works if compromise not initially run but prospective/post-hoc power was  
out <- p_t.test(n = 50, d = .5) |> Spover()  
update(out, beta_alpha=4)
```
