Title Analyzing the Orientation of Maximum Horizontal Stress

Version 0.4.8

Description Models the direction of the maximum horizontal stress using relative plate motion parameters. Statistical algorithms to evaluate the modeling results compared with the observed data. Provides plots to visualize the results. Methods described in Stephan et al. (2023) <doi:10.1038/s41598-023-42433-2> and Wdowinski (1998) <doi:10.1016/S0079-1946(98)00091-3>.

Contents

abs_vel *Absolute Plate Velocity*

Description

Calculates the absolute angular velocity of plate motion

Usage

```
abs_vel(w, alpha, r = earth_radius())
```

Arguments

w	Angular velocity or rate or angle of rotation
alpha	Angular distance to Euler pole or small circle around Euler pole
r	Radius. Default is WGS84 Earth's radius (6371.009 km)

Value

numeric (unit of velocity: km/Myr)

See Also

earth_radius()

Examples

```
abs_vel(0.21, 0)
abs_vel(0.21, 45)
abs_vel(0.21, 90)
```

angle-conversion *Degrees to Radians*

Description

Helper functions to transform between angles in degrees and radians.

Usage

```
rad2deg(rad)

deg2rad(deg)
```

Arguments

rad	(array of) angles in radians.
deg	(array of) angles in degrees.

Value

numeric. angle in degrees or radians.

Examples

```
deg2rad(seq(-90, 90, 15))
rad2deg(seq(-pi / 2, pi / 2, length = 13))
```

---

angle_vectors *Angle Between Two Vectors*

Description

Calculates the angle between two vectors

Usage

```
angle_vectors(x, y)
```

Arguments

x, y	Vectors in Cartesian coordinates. Can be vectors of three numbers or a matrix of 3 columns (x, y, z)

Value

numeric. angle in degrees

Examples

```
u <- c(1, -2, 3)
v <- c(-2, 1, 1)
angle_vectors(u, v) # 96.26395
```

axes *Plot axes*

Description

Show direction axes in a map

Usage

```
axes(
  x,
  y,
  angle,
  radius = 0.5,
  arrow.code = 1,
  arrow.length = 0,
  add = FALSE,
  ...
)
```

Arguments

x, y	coordinates of points
angle	Azimuth in degrees
radius	length of axis
arrow.code	integer. Kind of arrow head. The default is 1, i.e. no arrow head. See graphics::arrows() for details
arrow.length	numeric Length of the edges of the arrow head (in inches). (Ignored if arrow.code = 1)
add	logical. add to existing plot?
...	optional arguments passed to graphics::arrows()

Value

No return value, called for side effects

Examples

```
data("san_andreas")
axes(san_andreas$lon, san_andreas$lat, san_andreas$azi, add = FALSE)
```

circle_mean_diff *Circular Mean Difference*

Description

The circular mean difference is based on the sample circular distance

Usage

```
circular_mean_difference(x, w = NULL, axial = TRUE, na.rm = TRUE)

circular_mean_difference_alt(x, w = NULL, axial = TRUE, na.rm = TRUE)
```

Arguments

x	numeric vector. Values in degrees.
w	(optional) Weights. A vector of positive numbers and of the same length as x.
axial	logical. Whether the data are axial, i.e. pi-periodical (TRUE, the default) or directional, i.e. 2π-periodical (FALSE).
na.rm	logical value indicating whether NA values in x should be stripped before the computation proceeds.

Value

numeric

References

See Also

sample_circular_distance()

Examples

```
data("san_andreas")
circular_mean_difference(san_andreas$azi)
circular_mean_difference(san_andreas$azi, weighting(san_andreas$unc))

circular_mean_difference_alt(san_andreas$azi)
circular_mean_difference_alt(san_andreas$azi, weighting(san_andreas$unc))
```

`circle_stats` *Summary Statistics of Circular Data*

Description

Calculate the (weighted median) and standard deviation of orientation data.

Usage

```
circular_mean(x, w = NULL, axial = TRUE, na.rm = TRUE)

circular_var(x, w = NULL, axial = TRUE, na.rm = TRUE)

circular_sd(x, w = NULL, axial = TRUE, na.rm = TRUE)

circular_median(x, w = NULL, axial = TRUE, na.rm = TRUE)

circular_quantiles(x, w = NULL, axial = TRUE, na.rm = TRUE)

circular_IQR(x, w = NULL, axial = TRUE, na.rm = TRUE)
```

Arguments

`x`	numeric vector. Values in degrees.
`w`	(optional) Weights. A vector of positive numbers and of the same length as `x`.
`axial`	logical. Whether the data are axial, i.e. pi-periodical (`TRUE`, the default) or directional, i.e. 2π-periodical (`FALSE`).
`na.rm`	logical value indicating whether `NA` values in `x` should be stripped before the computation proceeds.

Value

numeric vector

Note

Weighting may be the reciprocal of the data uncertainties.

Weightings have no effect on quasi-median and quasi-quantiles if `length(x) %% 2 != 1` and `length(x) %% 4 == 0`, respectively.

circular_quantiles(sa.por$azi.PoR, w2)
```

`circular_dispersion_boot` *Bootstrapped Estimates for Circular Dispersion*

Description

Calculates bootstrapped estimates of the circular dispersion, its standard error and its confidence interval.

Usage

```
circular_dispersion_boot(
  x,
  y = NULL,
  w = NULL,
  w.y = NULL,
  R = 1000,
  conf.level = 0.95,
  ...
)
```

Arguments

x	numeric values in degrees.
y	numeric. The angle(s) about which the angles x disperse (in degrees).
w, w.y	(optional) Weights for x and y, respectively. A vector of positive numbers and of the same length as x.
R	The number of bootstrap replicates. positive integer (1000 by default).
conf.level	Level of confidence: $(1 - \alpha\%)/100$. (0.95 by default).
...	optional arguments passed to boot::boot()

Value

list containing:

MLE the maximum likelihood estimate of the circular dispersion

sde standard error of MLE

CI lower and upper limit of the confidence interval of MLE

See Also

circular_dispersion()

Examples

```
data("nuvel1")
PoR <- subset(nuvel1, nuvel1$plate.rot == "na")
sa.por <- PoR_shmax(san_andreas, PoR, "right")
circular_dispersion(sa.por$azi.PoR, y = 135, w = weighting(san_andreas$unc))
circular_dispersion_boot(sa.por$azi.PoR, y = 135, w = weighting(san_andreas$unc), R = 1000)
```

`circular_mode` *Circular Mode*

Description

MLE angle (maximum density) using a von Mises distribution kernel with specified concentration.

Usage

```
circular_mode(x, kappa = NULL, axial = TRUE, n = 512)
```

Arguments

`x`	numeric vector. Values in degrees.
`kappa`	von Mises distribution concentration parameter. Will be estimated using `est.kappa()` if not provided.
`axial`	logical. Whether the data are axial, i.e. pi-periodical (`TRUE`, the default) or directional, i.e. 2π-periodical (`FALSE`).#' @param kappa
`n`	the number of equally spaced points at which the density is to be estimated.

Value

numeric

References

N.I. Fisher (1993) Statistical Analysis of Circular Data, Cambridge University Press.

Examples

```
set.seed(1)
x <- rvm(10, 0, 100)
circular_mode(x, kappa = est.kappa(x))
```

`circular_qqplot` *Quantile-Quantile Linearised Plot for Circular Distributions*

Description

Uniformly distributed orientations should yield a straight line through the origin. Systematic departures from linearity will indicate preferred orientation.

Usage

```
circular_qqplot(
  x,
  axial = TRUE,
  xlab = paste("i/(n+1)"),
  ylab = NULL,
  main = "Circular Quantile-Quantile Plot",
  add_line = TRUE,
  col = "#B63679FF",
  ...
)
```

Arguments

x	numeric. Angles in degrees
axial	Logical. Whether data are uniaxial (axial=FALSE)
xlab, ylab, main	plot labels.
add_line	logical. Whether to connect the points by straight lines?
col	color for the dots.
...	graphical parameters

Value

plot

References

Borradaile, G. J. (2003). Statistics of earth science data: their distribution in time, space, and orientation (Vol. 351, p. 329). Berlin: Springer.

Examples

```
# von Mises distribution
x_vm <- rvm(100, mean = 0, kappa = 2)
circular_qqplot(x_vm, pch = 20)

x_norm <- rnorm(100, mean = 0, sd = 25)
circular_qqplot(x_norm, pch = 20)

# uniform (random) data
x_unif <- runif(100, 0, 360)
circular_qqplot(x_unif, pch = 20)
```

circular_range *Circular Range*

Description

Length of the smallest arc which contains all the observations. The circular range is based on the sample circular distance.

Usage

```
circular_range(x, axial = TRUE, na.rm = TRUE)
```

Arguments

x	numeric vector. Values in degrees.
axial	logical. Whether the data are axial, i.e. pi-periodical (TRUE, the default) or directional, i.e. 2π-periodical (FALSE).
na.rm	logical value indicating whether NA values in x should be stripped before the computation proceeds.

Value

numeric. angle in degrees

References

Mardia, K.V., and Jupp, P.E (1999). Directional Statistics, Wiley Series in Probability and Statistics. John Wiley & Sons, Inc., Hoboken, NJ, USA. doi:10.1002/9780470316979

See Also

sample_circular_distance()

Examples

```
roulette <- c(43, 45, 52, 61, 75, 88, 88, 279, 357)
circular_range(roulette, axial = FALSE)

data("san_andreas")
circular_range(san_andreas$azi)
```

`circular_sd_error` *Standard Error of Mean Direction of Circular Data*

Description

Measure of the chance variation expected from sample to sample in estimates of the mean direction (after Mardia 1972). It is a parametric estimate of the the circular standard error of the mean direction by the particular form of the standard error for the von Mises distribution. The approximated standard error of the mean direction is computed by the mean resultant length and the MLE concentration parameter κ.

Usage

```
circular_sd_error(x, w = NULL, axial = TRUE, na.rm = TRUE)
```

Arguments

`x`	numeric vector. Values in degrees.
`w`	(optional) Weights. A vector of positive numbers and of the same length as `x`.
`axial`	logical. Whether the data are axial, i.e. pi-periodical (`TRUE`, the default) or directional, i.e. 2π-periodical (`FALSE`).
`na.rm`	logical value indicating whether `NA` values in `x` should be stripped before the computation proceeds.

Value

numeric

```

`circular_summary` *Circular Summary Statistics*

Description

Circular mean, standard deviation, variance, quasi-quantiles, mode, 95% confidence angle, standardized skewness and kurtosis

Usage

```
circular_summary(
  x,
  w = NULL,
  axial = TRUE,
  mode = FALSE,
  kappa = NULL,
  fisher.CI = FALSE,
  conf.level = 0.95,
  na.rm = FALSE
)
```

Arguments

`x`	numeric vector. Values in degrees.
`w`	(optional) Weights. A vector of positive numbers and of the same length as `x`.
`axial`	logical. Whether the data are axial, i.e. pi-periodical (`TRUE`, the default) or directional, i.e. 2π-periodical (`FALSE`).
`mode`	logical. Whether the circular mode should be calculated or not.
`kappa`	numeric. von Mises distribution concentration parameter used for the circular mode. Will be estimated using `est.kappa()` if not provided.

`fisher.CI`	logical. Whether Fisher's or the default Mardia/Batchelet's confidence interval should be calculated.
`conf.level`	numeric. Level of confidence: $(1-\alpha\%)/100$. (`0.95` by default).
`na.rm`	logical value indicating whether `NA` values in `x` should be stripped before the computation proceeds.

Value

named vector

circular_summary(sa.por$azi.PoR, w = weighting(san_andreas$unc))
```

---

compact-grid *Compact Smoothed Stress Field*

Description

Filter smoothed stress field containing a range of search radii or kernel half widths to find shortest wavelength (R) with the least circular sd. or dispersion (or any statistic) for each coordinate, respectively.

Usage

```
compact_grid(x, type = c("stress", "dispersion"))

compact_grid2(x, ..., FUN = min)
```

Arguments

`x`	output of `stress2grid()`, `PoR_stress2grid()`, `stress2grid_stats()`, or `kernel_dispersion()`
`type`	character. Type of the grid `x`. Either `"stress"` (when input is `stress2grid()` or `PoR_stress2grid()`) or `"dispersion"` (when input is `kernel_dispersion()`).
`...`	`<tidy-select>` One unquoted expression separated by commas. Variable names can be used as if they were positions in the data frame. Variable must be a column in `x`.
`FUN`	function is used to aggregate the data using the search radius `R`. Default is `min()`.

Value

sf object

See Also

stress2grid(), PoR_stress2grid(), kernel_dispersion(), stress2grid_stats(), dplyr::dplyr_tidy_select()

Examples

```
data("san_andreas")
res <- stress2grid(san_andreas)
compact_grid(res) |> head()

## Not run:
res2 <- stress2grid_stats(san_andreas)
compact_grid2(res2, var, FUN = min)

## End(Not run)
```

---

confidence — *Confidence Interval around the Mean Direction of Circular Data after Batschelet (1971)*

Description

Probabilistic limit on the location of the true or population mean direction, assuming that the estimation errors are normally distributed.

Usage

```
confidence_angle(x, conf.level = 0.95, w = NULL, axial = TRUE, na.rm = TRUE)

confidence_interval(x, conf.level = 0.95, w = NULL, axial = TRUE, na.rm = TRUE)
```

Arguments

x	numeric vector. Values in degrees.
conf.level	Level of confidence: $(1 - \alpha\%)/100$. (0.95 by default).
w	(optional) Weights. A vector of positive numbers and of the same length as x.
axial	logical. Whether the data are axial, i.e. pi-periodical (TRUE, the default) or directional, i.e. 2π-periodical (FALSE).
na.rm	logical value indicating whether NA values in x should be stripped before the computation proceeds.

Details

The confidence angle gives the interval, i.e. plus and minus the confidence angle, around the mean direction of a particular sample, that contains the true mean direction under a given level of confidence.

Value

Angle in degrees

```

confidence_interval_fisher *Confidence Interval around the Mean Direction of Circular Data after Fisher (1993)*

Description

For large samples (n >=25) i performs are parametric estimate based on sample_circular_dispersion(). For smaller size samples, it returns a bootstrap estimate.

Usage

```
confidence_interval_fisher(
  x,
  conf.level = 0.95,
  w = NULL,
  axial = TRUE,
  na.rm = TRUE,
  boot = FALSE,
  R = 1000L,
  quiet = FALSE
)
```

Arguments

x	numeric vector. Values in degrees.
conf.level	Level of confidence: $(1 - \alpha\%)/100$. (0.95 by default).
w	(optional) Weights. A vector of positive numbers and of the same length as x.
axial	logical. Whether the data are axial, i.e. pi-periodical (TRUE, the default) or directional, i.e. 2π-periodical (FALSE).
na.rm	logical value indicating whether NA values in x should be stripped before the computation proceeds.
boot	logical. Force bootstrap estimation
R	integer. number of bootstrap replicates
quiet	logical. Prints the used estimation (parametric or bootstrap).

Value

coordinates *Coordinate Transformations*

Description

Converts vector between Cartesian and geographical coordinate systems

Usage

```
cartesian_to_geographical(n)

geographical_to_cartesian(p)

geographical_to_spherical(p)
```

Arguments

n	Cartesian coordinates (x, y, z) as vector
p	Geographical coordinates (latitude, longitude) as vector

Value

Functions return a (2- or 3-dimensional) vector representing a point in the requested coordinate system.

See Also

`cartesian_to_spherical()` and `spherical_to_cartesian()` for conversions to spherical coordinates

Examples

```
n <- c(1, -2, 3)
cartesian_to_geographical(n)
p <- c(50, 10)
geographical_to_cartesian(p)
```

`coordinates2` *Coordinate Transformations*

Description

Converts vector between Cartesian and spherical coordinate systems

Usage

```
cartesian_to_spherical(n)

spherical_to_cartesian(p)

spherical_to_geographical(p)
```

Arguments

`n`	Cartesian coordinates (x, y, z) as three-column vector
`p`	Spherical coordinates (colatitude, azimuth) as two-column vector

Value

Functions return a (2- or 3-dimensional) vector representing a point in the requested coordinate system.

See Also

`cartesian_to_geographical()` and `geographical_to_cartesian()` for conversions to geographical coordinates

Examples

```
n <- c(1, -2, 3)
cartesian_to_spherical(n) # 36.699, -63.435
p <- c(50, 10)
spherical_to_cartesian(p) # 0.75, 0.13, 0.64
```

coordinate_mod *Coordinate Correction*

Description

Corrects the longitudes or latitudes to value between -180.0 and 180.0 or -90 and 90 degree

Usage

```
longitude_modulo(x)

latitude_modulo(x)
```

Arguments

x	Longitude(s) or latitude(s) in degrees

Value

numeric

Examples

```
longitude_modulo(-361 + 5 * 360) # -1

cpm_models *Global model of current plate motions*

Description

Compilation of global models for current plate motions, including NUVEL1 (DeMets et al. 1990), NNR-NUVEL1A (DeMets et al., 1990), NNR-MORVEL56 (Argus et al., 2011), REVEL (Sella et al., 2002), GSRM2.1 (Kreemer et al., 2014), HS2-NUVEL1 (Gripp and Gordon, 1990), HS3-NUVEL1A (Gripp and Gordon, 2002), P073 (Chase 1978), AM1-2 (Minster and Jordan, 1978), ITRF2020-PPM (Altamimi et al. 2023), and PB2002 (Bird, 2003)

Usage

```
data('cpm_models')
```

Format

list containing objects of class `data.frame`

plate.name The rotating plate

plate.rot The abbreviation of the plate's name

lat,lon Coordinates of the Pole of Rotation

angle The amount of rotation (angle in 1 Myr)

plate.fix The anchored plate, i.e. `plate.rot` moves relative to `plate.fix`

model Model for current global plate motion

Examples

```
data("cpm_models")
head(cpm_models[[1]])
```

data2PoR *Transforms coordinates and azimuths into PoR coordinates system*

Description

Convenience function to add PoR coordinates and PoR azimuths to data

Usage

```
data2PoR(x, PoR)
```

Arguments

x	sf object or a data.frame containing the coordinates of the point(s) (lat, lon columns). x must contain the direction of σ_{Hmax} as column azi, its standard deviation (column unc) is optional).
PoR	data.frame or object of class euler.pole containing the geographical coordinates of the Eule pole.

Value

sf object in PoR CRS with additional columns lon.PoR, lat.PoR, and azi.PoR

Examples

```
por <- subset(nuvel1, nuvel1$plate.rot == "na")
data2PoR(san_andreas, por)
```

deviation_norm *Normalize Angle Between Two Directions*

Description

Normalizes the angle between two directions to the acute angle in between, i.e. angles between 0 and 90°

Usage

```
deviation_norm(x, y = NULL)
```

Arguments

x, y	Minuend and subtrahend. Both numeric vectors of angles in degrees. If y is missing, it treats x as difference. If not, length of subtrahend y is either 1 or equal to length(x).

Value

numeric vector, acute angles between two directions, i.e. values between 0 and 90°

Author(s)

Tobias Stephan

Examples

```
deviation_norm(175, 5)
deviation_norm(c(175, 95, 0), c(5, 85, NA))
deviation_norm(c(-5, 85, 95, 175, 185, 265, 275, 355, 365))
```

`deviation_shmax` *Deviation of Observed and Predicted Directions of Maximum Horizontal Stress*

Description

Calculate the angular difference between the observed and modeled direction of maximum horizontal stresses (σ_{Hmax}) along great circles, small circles, and loxodromes of the relative plate motion's Euler pole

Usage

```
deviation_shmax(prd, obs)
```

Arguments

`prd`	`data.frame` containing the modeled azimuths of σ_{Hmax}, i.e. the return object from `model_shmax()`
`obs`	Numeric vector containing the observed azimuth of σ_{Hmax}, same length as `prd`

Details

Deviation is positive for counterclockwise deviation of observed azimuth wrt. predicted azimuth.

Value

An object of class `data.frame`

dev.gc Deviation of observed stress from modeled σ_{Hmax} following great circles

dev.sc Small circles

dev.ld.cw Clockwise loxodromes

dev.ld.ccw Counter-clockwise loxodromes

Author(s)

Tobias Stephan

See Also

`model_shmax()` to calculate the theoretical direction of σ_{Hmax}.

Examples

```
data("nuvel1")
# North America relative to Pacific plate:
PoR <- subset(nuvel1, nuvel1$plate.rot == "na")

# the point where we want to model the SHmax direction:
point <- data.frame(lat = 45, lon = 20)

prd <- model_shmax(point, PoR)
deviation_shmax(prd, obs = 90)
```

---

dispersion *Circular Distance and Dispersion*

Description

Circular distance between two angles and circular dispersion of angles about a specified angle.

Usage

```
circular_distance(x, y, axial = TRUE, na.rm = TRUE)

circular_dispersion(
  x,
  y = NULL,
  w = NULL,
  w.y = NULL,
  axial = TRUE,
  na.rm = TRUE
)

circular_sd2(x, y, w = NULL, axial = TRUE, na.rm = TRUE)
```

Arguments

x, y	vectors of numeric values in degrees. length(y) is either 1 or length(x)
axial	logical. Whether the data are axial, i.e. pi-periodical (TRUE, the default) or directional, i.e. 2π-periodical (FALSE).
na.rm	logical. Whether NA values in x should be stripped before the computation proceeds.
w, w.y	(optional) Weights. A vector of positive numbers and of the same length as x. w.y is the (optional) weight of y.

Details

Circular dispersion is a measure for the spread of data like the variance. Dispersion measures the spread about a given angles, whereas the variance measures the spread about the mean (Mardia and Jupp, 1999). When y = NULL the dispersion is identical to the variance.

Circular standard deviation in circular_sd2() is the transformed dispersion instead of the variance as for circular_sd().

Value

circular_distance returns a numeric vector of positive numbers, circular_dispersion and circular_sd2() return a positive number.

Note

If y is NULL, than the circular variance is returned.

See Also

circular_mean(), circular_var().

Examples

```
a <- c(0, 2, 359, 6, 354)
circular_distance(a, 10) # distance to single value

b <- a + 90
circular_distance(a, b) # distance to multiple values

data("nuvel1")
PoR <- subset(nuvel1, nuvel1$plate.rot == "na")
sa.por <- PoR_shmax(san_andreas, PoR, "right")
```

```
circular_dispersion(sa.por$azi.PoR, y = 135)
circular_dispersion(sa.por$azi.PoR, y = 135, w = weighting(san_andreas$unc))
circular_sd2(sa.por$azi.PoR, y = 135, w = weighting(san_andreas$unc))
```

`distance_binned_stats` *Distance Binned Summary Statistics*

Description

[Experimental] Circular summary statistics over intervals of distances.

Usage

```
distance_binned_stats(
  azi,
  distance,
  n.breaks = 10,
  width.breaks = NULL,
  unc = NULL,
  prd = NULL,
  prd.error = NULL,
  kappa = 2,
  R = 1000,
  conf.level = 0.95,
  ...
)
```

Arguments

`azi`	numeric. Azimuth values in degrees.
`distance`	numeric. the independent variable along the values in `azi` are sorted, e.g. the plate boundary distances
`n.breaks`	numeric. number (greater than or equal to 2) giving the number of equal-sized intervals into which `distance` is to be cut. Default is 10. Will be ignored if `width.breaks` is specified.
`width.breaks`	numeric. The width of the intervals into which `distance` is to be cut.
`unc`	(optional) Uncertainties of `azi` (in degrees) acting as inverse weighting factors for statistics.
`prd`	(optional) numeric. A predicted orientation in degrees.
`prd.error`	(optional) numeric. The uncertainty of the predicted orientation in degrees.
`kappa`	numeric. Concentration parameter applied for the circular mode.
`R`	integer. Number of bootstrap iterates for estimating the error of the dispersion.
`conf.level`	The level of confidence for confidence interval and bootstrapped standard error of dispersion.
`...`	optional arguments passed to `ggplot2::cut_number()` and `ggplot2::cut_width()`

Value

tibble containing the n values for aziin each bin, min/median/max distance of the bin, and the summary statistics for azi. If prd is specified, the normal Chi-squared statistic, dispersion and its standard error are returned as well.

See Also

circular_summary(), circular_dispersion(), and circular_dispersion_boot()

Examples

```
data("plates")
plate_boundary <- subset(plates, plates$pair == "na-pa")
data("san_andreas")
PoR <- subset(nuvel1, nuvel1$plate.rot == "na")
san_andreas$distance <- distance_from_pb(
  x = san_andreas,
  PoR = PoR,
  pb = plate_boundary,
  tangential = TRUE
)
dat <- san_andreas |> cbind(PoR_shmax(san_andreas, PoR, "right"))

distance_binned_stats(dat$azi.PoR,
  distance = dat$distance, width.breaks = 1,
  unc = dat$unc, prd = 135
) |> head()
```

---

distance_from_pb *Distance from plate boundary*

Description

Absolute distance of data points from the nearest plate boundary

Usage

```
distance_from_pb(x, PoR, pb, tangential = FALSE, km = FALSE, ...)
```

Arguments

x	sf or data.frame objects of the data points in geographical coordinate system
PoR	Pole of Rotation. "data.frame" or object of class "euler.pole" containing the geographical coordinates of the Pole of Rotation
pb	sf objects of the plate boundary geometries in the geographical coordinate system
tangential	Logical. Whether the plate boundary is a tangential boundary (TRUE) or an inward and outward boundary (FALSE, the default).

km	Logical. Whether the distance is expressed in kilometers (TRUE) or in degrees (FALSE, the default).
...	optional arguments passed to smoothr::densify()

Details

The distance to the plate boundary is the longitudinal or latitudinal difference between the data point and the plate boundary (along the closest latitude or longitude) for inward/outward or tangential plate boundaries, respectively.

Value

Numeric vector of the great circle distances in units defined by km.

Note

Stresses emanate from the plate boundary along great circles, small circles or loxodromes associated with the pole of rotation. Hence the emanation distance is not necessarily the shortest distance to the plate boundary, which is measured along a great circle unrelated to the pole of rotation. The differences are particularly notable when the plate boundary is kinked or for convergent and divergent plate boundaries.

Examples

```
data("nuvel1")
na_pa <- subset(nuvel1, nuvel1$plate.rot == "na")

data("plates")
plate_boundary <- subset(plates, plates$pair == "na-pa")

data("san_andreas")
res <- distance_from_pb(
  x = san_andreas, PoR = na_pa, pb = plate_boundary, tangential = TRUE
)
head(res)

res.km <- distance_from_pb(
  x = san_andreas, PoR = na_pa, pb = plate_boundary, tangential = TRUE, km = TRUE
)
range(res.km)
```

`dist_greatcircle` *Distance between points*

Description

Returns the great circle distance between a location and all grid point in km

Usage

```
dist_greatcircle(
  lat1,
  lon1,
  lat2,
  lon2,
  r = earth_radius(),
  method = c("haversine", "orthodrome", "vincenty", "euclidean")
)
```

Arguments

`lat1`, `lon1`	numeric vector. coordinate of point(s) 1 (degrees).
`lat2`, `lon2`	numeric vector. coordinates of point(s) 2 (degrees).
`r`	numeric. radius of the sphere (default = 6371.0087714 km, i.e. the radius of the Earth)
`method`	Character. Formula for calculating great circle distance, one of:
	`"haversine"` great circle distance based on the haversine formula that is optimized for 64-bit floating-point numbers (the default)
	`"orthodrome"` great circle distance based on the spherical law of cosines
	`"vincenty"` distance based on the Vincenty formula for an ellipsoid with equal major and minor axes
	`"euclidean"` Euclidean distance (not great circle distance!)

Value

numeric vector with length equal to `length(lat1)` or `length(lat2)`

See Also

`orthodrome()`, `haversine()`, `vincenty()`

Examples

```
# Haversine: (4149.157, 2296.583) km
dist_greatcircle(lat1 = 20, lon1 = 12, lat2 = c(50, 30), lon2 = c(40, 32))

# Orthodrome: (4149.157, 2296.583) km
```

```
dist_greatcircle(
  lat1 = 20, lon1 = 12, lat2 = c(50, 30), lon2 = c(40, 32),
  method = "orthodrome"
)

# Vincenty: (4149.157, 2296.583) km
dist_greatcircle(
  lat1 = 20, lon1 = 12, lat2 = c(50, 30), lon2 = c(40, 32),
  method = "vincenty"
)

# Euclidean (4076.220, 2284.169) km
dist_greatcircle(
  lat1 = 20, lon1 = 12, lat2 = c(50, 30), lon2 = c(40, 32),
  method = "euclidean"
)
```

`earth_radius` *Earth's radius in km*

Description

IERS mean radius of Earth in km (based on WGS 84)

Usage

```
earth_radius()
```

Value

numeric value

`equivalent_rotation` *Equivalent rotation*

Description

Transforms a sequence of rotations into a new reference system

Usage

```
equivalent_rotation(x, fixed, rot)
```

Arguments

x	Object of class "data.frame" containing the Euler poles of plate rotations: plate.rot Moving plate lat, lon coordinates of Euler pole angle Angle of rotation plate.fix Fixed plate
fixed	plate that will be regarded as fixed. Has to be one out of x$plate.fix
rot	(optional) plate that will be regarded as rotating. Has to be one out of x$plate.rot.

Value

sequence of plate rotations in new reference system. Same object class as x

See Also

relative_rotation()

Examples

```
data(nuvel1) # load the NUVEL1 rotation parameters

# all nuvel1 rotation equivalent to fixed Africa:
equivalent_rotation(nuvel1, fixed = "af")
# relative plate motion between Eurasia and India:
equivalent_rotation(nuvel1, "eu", "in") # lat = 24.58, lon = 18.07, angle = 0.528
```

---

estimate-kappa *Concentration parameter of von Mises distribution*

Description

Estimates the concentration parameter of a von Mises distribution, given a set of angular measurements.

Usage

```
est.kappa.MLE(x, w = NULL, bias = FALSE)

est.kappa(x, w = NULL, p = 2)
```

Arguments

x	numeric. angles in degrees
w	numeric. weightings
bias	logical parameter determining whether a bias correction is used in the computation of the MLE. Default for bias is FALSE for no bias correction.
p	integer. Number of parameters in the data space: 2 for circle (the default), 3 for a sphere.

Details

`est.kappa.MLE()` is the maximum likelihood estimate for MLE for κ.

`est.kappa()` uses an approximation based on the empirical equation:

$$\kappa = \frac{\bar{R}(p - \bar{R}^2)}{1 - \bar{R}^2}$$

where $\bar{R}$ is the mean resultant length and p is the dimensionality of the data (2 for circular data).

Value

numeric. Concentration of a von Mises distribution

Examples

```
set.seed(123)
x <- rvm(100, 90, 10)
w <- weighting(runif(100, 0, 10))

est.kappa(x, w)

est.kappa.MLE(x, w)
```

`euler_pole` *Euler pole object*

Description

Creates an object of the orientation of the Euler pole axis

Usage

```
euler_pole(x, y, z = NA, geo = TRUE, angle = NA)
```

Arguments

`x`	latitude or x coordinate of Euler pole axis
`y`	longitude or y
`z`	z coordinate
`geo`	logical, `TRUE` (the default) if Euler pole axis is given in geographical coordinates (latitude, longitude). `FALSE` if given in Cartesian coordinates (`x`, `y`, `z`)
`angle`	(optional) Angle of rotation in degrees (CCW rotation if angle is positive)

Value

An object of class `"euler.pole"` containing the Euler pole axis in both geographical and Cartesian coordinates and the angle of rotation in radians.

Examples

```
euler_pole(90, 0, angle = 45)
euler_pole(0, 0, 1, geo = FALSE)
```

`geom_azimuth` *Azimuth visualization*

Description

`geom_azimuth()` visualizes axial-directional vector fields using a geom to produce a new graphical layer, which allows aesthetic options. This layer can be overlaid on a map to improve visualisation of mapped data. The geom draws line segments (spokes) centered at (x, y) with a given orientation (`angle` in degrees) and length (`radius`). By default the spoke is centered using `PositionCenterSpoke`, so that the given coordinates mark the middle of the line. The azimuths are given as angles in degrees increasing clockwise from North.

Usage

```
geom_azimuth(
  mapping = NULL,
  data = NULL,
  stat = "azimuth",
  center = TRUE,
  radius = NULL,
  na.rm = FALSE,
  show.legend = NA,
  inherit.aes = TRUE,
  ...
)
```

Arguments

`mapping`	Set of aesthetic mappings created by `ggplot2::aes()`.
`data`	A data frame. If `NULL`, the default, the data is inherited from the plot data as specified in the call to `ggplot2::ggplot()`.
`stat`	The statistical transformation to use on the data. Defaults to `"identity"`.
`center`	Logical; if `TRUE` (the default) spokes are centered on (x, y) using `PositionCenterSpoke` - useful for axial data. If `FALSE`, behaves like `ggplot2::geom_spoke()` (line starts at (x, y)) - useful for directional data (especially when in combination with `arrow()`).
`radius`	Length of spoke
`na.rm`	If `FALSE`, the default, missing values are removed with a warning. If `TRUE`, missing values are silently removed.
`show.legend`	Logical. Should this layer be included in the legends?
`inherit.aes`	If `FALSE`, overrides the default aesthetics, rather than combining with them.
`...`	Other arguments passed on to `ggplot2::layer()`. These are often aesthetics (e.g. `colour`, `linetype`, `linewidth`, `alpha`).

Value

A ggplot2 layer that adds axis-like spokes.

Aesthetics

`geom_azimuth()` understands the following aesthetics (required aesthetics in **bold**):

- **x**
- **y**
- angle (in degrees, transformed internally)
- radius
- colour
- alpha
- linewidth
- linetype

See Also

`ggplot2::geom_spoke()`, `geom_azimuthpoint()`

Examples

```
set.seed(20250411)
df <- data.frame(
  x = runif(5), y = runif(5),
  angle_deg = rvm(5, mean = 90, kappa = 10),
  radius = runif(5, 0.1, 2)
)

if (require("ggplot2")) {
  ggplot(df, aes(x, y)) +
    geom_azimuth(aes(angle = angle_deg), radius = .1, linewidth = 1.2, colour = "blue")
  if (require("grid")) {
    ggplot(df, aes(x, y, radius = radius)) +
    geom_azimuth(aes(angle = angle_deg), center = FALSE, colour = "red", arrow = grid::arrow())
  }
}
```

`geom_azimuthpoint` *Azimuth + point visualization*

Description

`geom_azimuthpoint()` draws line segments (spokes) like `geom_azimuth()`, but also places a point (marker) at the spoke's center `(x, y)`.

Aesthetic rules:

- `linewidth`, `linetype` affect the spoke only
- `shape` affects the point only
- `colour`, `alpha` affect both spoke and point
- `size` sets the size of the point only

Usage

```
geom_azimuthpoint(
  mapping = NULL,
  data = NULL,
  stat = "identity",
  center = TRUE,
  na.rm = FALSE,
  show.legend = NA,
  inherit.aes = TRUE,
  size = 2,
  ...
)
```

Arguments

`mapping`	Set of aesthetic mappings created by `ggplot2::aes()`.
`data`	A data frame. If `NULL`, the default, the data is inherited from the plot data as specified in the call to `ggplot2::ggplot()`.
`stat`	The statistical transformation to use on the data. Defaults to `"identity"`.
`center`	Logical; if `TRUE` spokes are centered on (x, y) using `PositionCenterSpoke`. If `FALSE`, behaves like `ggplot2::geom_spoke()` (line starts at (x, y)).
`na.rm`	If `FALSE`, the default, missing values are removed with a warning. If `TRUE`, missing values are silently removed.
`show.legend`	Logical. Should this layer be included in the legends?
`inherit.aes`	If `FALSE`, overrides the default aesthetics, rather than combining with them.
`size`	Size of the point marker (default = 2).
`...`	Other arguments passed on to `geom_azimuth()` and `ggplot2::geom_point()`. These may include `arrow`, `fill`, etc.

Value

A list of ggplot2 layers (spokes + points).

Aesthetics

`geom_azimuthpoint()` understands the following aesthetics (required aesthetics in **bold**):

- **x**
- **y**
- angle (in degrees, transformed internally; spoke only)
- radius (spoke only)
- colour (shared)
- alpha (shared)
- linewidth (spoke only)
- linetype (spoke only)
- shape (point only)
- size (point only, or via argument)
- fill (point only, for shapes that accept fill)

See Also

`geom_azimuth()`, `ggplot2::geom_spoke()`, `ggplot2::geom_point()`

Examples

```
set.seed(20250411)
df <- data.frame(
  x = runif(5), y = runif(5),
  angle_deg = rvm(5, mean = 90, kappa = 10),
  radius = runif(5, 0.1, 1),
  group = rep(1:2, length.out = 5)
)

if (require("ggplot2")) {
  ggplot(data = df, aes(x, y, angle = angle_deg, radius = radius)) +
    geom_azimuthpoint(aes(colour = factor(group), shape = factor(group)),
      linewidth = 1.1, linetype = "dashed",
      size = 3, alpha = 0.8
    )
}
```

`get_azimuth` *Azimuth Between two Points*

Description

Calculate initial bearing (or forward azimuth/direction) to go from point `a` to point `b` following great circle arc on a sphere.

Usage

```
get_azimuth(lat_a, lon_a, lat_b, lon_b)
```

Arguments

lat_a, lat_b	Numeric. Latitudes of a and b (in degrees).
lon_a, lon_b	Numeric. Longitudes of a and b (in degrees).

Details

get_azimuth() is based on the spherical law of tangents. This formula is for the initial bearing (sometimes referred to as forward azimuth) which if followed in a straight line along a great circle arc will lead from the start point a to the end point b.

$$\theta = \arctan 2(\sin \Delta\lambda \cos \psi_2, \cos \psi_1 \sin \psi_1 - \sin \psi_1 \cos \psi_2 \cos \Delta\lambda)$$

where ψ_1, λ_1 is the start point, ψ_2, λ_2 the end point ($\Delta\lambda$ is the difference in longitude).

Value

numeric. Azimuth in degrees

import_WSM *World Stress Map Database (WSM)*

Description

Download WSM2025 or WSM2016 database from the GFZ sever and applies optional filters. If destdir is specified, the data can be reloaded in a later R session using load_WSM() using the same arguments.

Usage

```
download_WSM(
  destdir = tempdir(),
  load = TRUE,
  version = c("2025", "2016"),
  ...
)

load_WSM(
  file,
  quality = c("A", "B", "C", "D", "E", "X"),
  lat_range = c(-90, 90),
  lon_range = c(-180, 180),
  depth_range = c(-Inf, Inf),
 type = c("BO", "BOC", "BOT", "BS", "DIF", "FMA", "FMF", "FMS", "GFI", "GFM", "GFS",
  "GVA", "HF", "HFG", "HFM", "HFH", "HFP", "HFS", "OC", "PC", "SWB", "SWL", "SWS"),
  regime = c("N", "NS", "T", "TS", "S", NA)
)

download_WSM2016(destdir = tempdir(), load = TRUE, ...)

load_WSM2016(
  file,
  quality = c("A", "B", "C", "D", "E"),
  lat_range = c(-90, 90),
  lon_range = c(-180, 180),
  depth_range = c(-Inf, Inf),
 type = c("BO", "BOC", "BOT", "BS", "DIF", "FMA", "FMF", "FMS", "GFI", "GFM", "GFS",
    "GVA", "HF", "HFG", "HFM", "HFP", "OC", "PC", "SWB", "SWL", "SWS"),
  regime = c("N", "NS", "T", "TS", "S", NA)
)
```

Arguments

destdir	where to save files, defaults to base::tempdir(), base::getwd() is also possible.
load	TRUE load the dataset into R, FALSE return the file name of the downloaded object.
version	character. Version of the World stress map database. Either "2025" (default) or "2016"
...	(optional) arguments passed to load_WSM()
file	the name of the file which the data are to be read from.
quality	a character vectors containing the quality levels to be included. Includes all quality ranks (A-X) by default.
lat_range, lon_range	two-element numeric vectors giving the range of latitudes and longitudes (in degrees).

depth_range	two-element numeric vectors giving the depth interval (in km)
type	a character vectors containing the methods of stress inversion to be included. Includes all methods by default. See WSM2016 manual for used acronyms.
regime	a character vectors containing the stress regimes to be included. Acronyms: "N" - normal, "T" - thrust, "S" - strike-slip, "NS" - oblique normal, "TS" - oblique thrust, and NA - unknown faulting

Value

sf object of and the parsed numeric uncertainty (unc) based on the reported standard deviation and the quality rank. If load=FALSE, the path to the downloaded file is returned.

Note

Because of R-compatibility and easy readability reasons, the downloaded dataset is a modified version of the original, WSM server version: All column names have been changed from uppercase (in the original dataset) to lowercase characters. Unknown azimuth values are represented by NA values instead of 999 in the original. Unknown regimes are represented by NA instead of "U" in the original.

Examples

```
## Not run:
download_WSM(
  quality = c("A", "B", "C"), lat_range = c(51, 72),
  lon_range = c(-180, -130), depth_range = c(0, 10), type = "FMS"
)

## End(Not run)
```

is.euler *Check if object is euler.pole*

Description

Check if object is euler.pole

Usage

```
is.euler(x)
```

Arguments

x	object of class "euler.pole"

Value

logical

kuiper_test *Kuiper Test of Circular Uniformity*

Description

Kuiper's test statistic is a rotation-invariant Kolmogorov-type test statistic. The critical values of a modified Kuiper's test statistic are used according to the tabulation given in Stephens (1970).

Usage

```
kuiper_test(x, alpha = 0, axial = TRUE, quiet = FALSE)
```

Arguments

x	numeric vector containing the circular data which are expressed in degrees
alpha	Significance level of the test. Valid levels are 0.01, 0.05, and 0.1. This argument may be omitted (NULL, the default), in which case, a range for the p-value will be returned.
axial	logical. Whether the data are axial, i.e. π-periodical (TRUE, the default) or circular, i.e. 2π-periodical (FALSE).
quiet	logical. Prints the test's decision.

Details

If statistic > p.value, the null hypothesis is rejected. If not, randomness (uniform distribution) cannot be excluded.

Value

list containing the test statistic `statistic` and the significance level `p.value`.

Examples

```
# Example data from Mardia and Jupp (1999), pp. 93
pidgeon_homing <- c(55, 60, 65, 95, 100, 110, 260, 275, 285, 295)
kuiper_test(pidgeon_homing, alpha = .05)

# San Andreas Fault Data:
data(san_andreas)
data("nuvel1")
PoR <- subset(nuvel1, nuvel1$plate.rot == "na")
sa.por <- PoR_shmax(san_andreas, PoR, "right")
kuiper_test(sa.por$azi.PoR, alpha = .05)
```

---

line_azimuth *Extract azimuths of line segments*

Description

Extract azimuths of line segments

Usage

```
line_azimuth(x, warn = TRUE)

lines_azimuths(x)
```

Arguments

x	sf object of type "LINESTRING" or "MULTILINESTRING"
warn	logical; if TRUE, warn if "MULTILINESTRING" (default).

Details

It is recommended to perform `line_azimuth()` on single line objects, i.e. type "LINESTRING", instead of "MULTILINESTRING". This is because the azimuth of the last point of a line will be calculated to the first point of the next line otherwise. This will cause a warning message (if `warn = TRUE`). For "MULTILINESTRING" objects, use `lines_azimuths()`.

Value

sf object of type "POINT" with the columns and entries of the first row of `x`

Examples

```
data("plates")

# one line:
subset(plates, pair == "af-eu") |>
  smoothr::densify() |>
  line_azimuth() |>
  head()

# multiple lines:
lines_azimuths(plates[1:5, ]) |> head()
```

`mean_resultant_length` *Mean Resultant Length*

Description

Measure of spread around the circle. It should be noted that: If R=0, then the data is completely spread around the circle. If R=1, the data is completely concentrated on one point.

Usage

```
mean_resultant_length(x, w = NULL, na.rm = TRUE)
```

Arguments

`x`	numeric vector. Values in degrees, for which the mean, median or standard deviation are required.
`w`	(optional) Weights. A vector of positive numbers, of the same length as `x`.
`na.rm`	logical value indicating whether `NA` values in `x` should be stripped before the computation proceeds.

Value

numeric.

Examples

```
# Example data from Davis (1986), pp. 316
finland_stria <- c(
  23, 27, 53, 58, 64, 83, 85, 88, 93, 99, 100, 105, 113,
  113, 114, 117, 121, 123, 125, 126, 126, 126, 127, 127, 128, 128, 129, 132,
  132, 132, 134, 135, 137, 144, 145, 145, 146, 153, 155, 155, 155, 157, 163,
  165, 171, 172, 179, 181, 186, 190, 212
)
mean_resultant_length(finland_stria, w = NULL, na.rm = FALSE) # 0.800
```

`model_shmax` *Theoretical Direction of Maximum Horizontal Stress in the geographical reference system.*

Description

Models the direction of maximum horizontal stress σ_{Hmax} along great circles, small circles, and loxodromes at a given point or points according to the relative plate motion in the geographical coordinate reference system.

Usage

```
model_shmax(df, euler)
```

Arguments

`df`	`data.frame` containing the coordinates of the point(s) (`lat`, `lon`).
`euler`	`"data.frame"` or object of class `"euler.pole"` containing the geographical coordinates of the Euler pole

Details

σ_{Hmax} following *great circles* is the (initial) bearing between the given point and the pole of relative plate motion. σ_{Hmax} along *small circles*, clockwise, and counter-clockwise *loxodromes* is 90°, +45°, and 135° (-45°) to this great circle bearing, respectively.

Value

`data.frame`

gc Azimuth of modeled σ_{Hmax} following great circles

sc Small circles

ld.cw Clockwise loxodromes

ld.ccw Counter-clockwise loxodromes

Author(s)

Tobias Stephan

References

Stephan, T., Enkelmann, E., and Kroner, U. "Analyzing the horizontal orientation of the crustal stress adjacent to plate boundaries". *Sci Rep* 13. 15590 (2023). doi:10.1038/s41598023424332.

See Also

`deviation_shmax()` to compute the deviation of the modeled direction from the observed direction of σ_{Hmax}. `PoR_shmax()` to calculate the azimuth of σ_{Hmax} in the pole of rotation reference system.

Examples

```
data("nuvel1")
# North America relative to Pacific plate:
euler <- subset(nuvel1, nuvel1$plate.rot == "na")

# the point where we mant to model the SHmax direction:
point <- data.frame(lat = 45, lon = 20)

model_shmax(point, euler)
```

`norm_chisq` *Normalized Chi-Squared Test for Circular Data*

Description

A quantitative comparison between the predicted and observed directions of σ_{Hmax} is obtained by the calculation of the average azimuth and by a normalized χ^2 test.

Usage

```
norm_chisq(obs, prd, unc)
```

Arguments

`obs`	Numeric vector containing the observed azimuth of σ_{Hmax}, same length as `prd`
`prd`	Numeric vector containing the modeled azimuths of σ_{Hmax}, i.e. the return object from `model_shmax()`
`unc`	Uncertainty of observed σ_{Hmax}, either a numeric vector or a number

Details

The normalized χ^2 test is

$$Norm\chi_i^2 == \frac{\sum_{i=1}^{M}\left(\frac{\alpha_i - \alpha_{predict}}{\sigma_i}\right)^2}{\sum_{i=1}^{M}\left(\frac{90}{\sigma_i}\right)^2}$$

The value of the chi-squared test statistic is a number between 0 and 1 indicating the quality of the predicted σ_{Hmax} directions. Low values (≤ 0.15) indicate good agreement, high values (> 0.7) indicate a systematic misfit between predicted and observed σ_{Hmax} directions.

Value

Numeric vector

nuvel1 *NUVEL-1 Global model of current plate motions*

Description

NNR-NUVEL-1 global model of current plate motions by DeMets et al. 1990

Usage

```
data('nuvel1')
```

Format

An object of class `data.frame`

plate.name The rotating plate

plate.rot The abbreviation of the plate's name

lat,lon Coordinates of the Pole of Rotation

angle The amount of rotation (angle in 1 Myr)

plate.fix The anchored plate, i.e. `plate.rot` moves relative to `plate.fix`

source Reference to underlying study

References

Examples

```
data("nuvel1_plates")
head("nuvel1_plates")
```

`ort-eigen` *Decomposition of Orientation Tensor in 2D*

Description

Spectral decomposition of the 2D orientation tensor into two Eigenvectors and corresponding Eigenvalues provides provides a measure of location and a corresponding measure of dispersion, respectively.

Usage

```
ot_eigen2d(x, w = NULL, scale = FALSE)

principal_direction(x, w = NULL)

axial_strength(x, w = NULL)

axial_dispersion(x, w = NULL)
```

Arguments

x	numeric. Axial angular data (in degrees).
w	(optional) Weights. A vector of positive numbers and of the same length as x.
scale	logical. Whether the Eigenvalues should be scaled so they sum up to 1. Only applicable when weighting are specified, otherwise the eigenvalues are always scaled.

Details

The **Eigenvalues** ($\lambda_1 > \lambda_2$) can be interpreted as the fractions of the variance explained by the orientation of the associated Eigenvectors. The two perpendicular **Eigenvectors** (a_1, a_2) are the "principal directions" with respect to the highest and the lowest concentration of orientation data.

The strength of the orientation is the largest eigenvalue λ_1 normalized by the sum of the eigenvalues (`scale=TRUE`). Then $\lambda_2 = 1 - \lambda_1$ is a **measure of dispersion** of 2D orientation data with respect to a_1.

Value

`ot_eigen2d` returns a list of the Eigenvalues and the axial angles corresponding to the Eigenvectors. `principal_direction()`, `axial_strength()` and `axial_dispersion()` are convenience functions to return the orientation of the largest eigenvalue, the orientation strength, the axial dispersion respectively.

Note

Eigenvalues and Eigenvectors of the orientation tensor (inertia tensor) are also called "principle moments of inertia" and "principle axes of inertia", respectively.

See Also

`ortensor2d()`

Examples

```
test <- rvm(100, mean = 0, k = 10) / 2
ot_eigen2d(test)

data("nuvel1")
PoR <- subset(nuvel1, nuvel1$plate.rot == "na")
sa.por <- PoR_shmax(san_andreas, PoR, "right")
sa_eig <- ot_eigen2d(sa.por$azi.PoR, w = weighting(san_andreas$unc), scale = TRUE)
print(sa_eig)

rose(sa.por$azi.PoR, muci = FALSE)
rose_line(sa_eig$vectors,
  col = c("red", "green"),
  radius = sa_eig$values, lwd = 2
)
graphics::legend("topright",
```

```
  legend = round(sa_eig$values, 2),
  col = c("red", "green"), lty = 1
)

principal_direction(sa.por$azi.PoR)

axial_strength(sa.por$azi.PoR)

axial_dispersion(sa.por$azi.PoR)
```

`ortensor2d` *Orientation Tensor*

Description

2D orientation tensor characterizes distribution of axial angles using the Eigenvalue method (Watson 1966, Scheidegger 1965).

Usage

```
ortensor2d(x, w = NULL, norm = FALSE)
```

Arguments

`x`	numeric. Axial angular data (in degrees).
`w`	(optional) Weights. A vector of positive numbers and of the same length as `x`.
`norm`	logical. Whether the tensor should be normalized.

Details

The moment of inertia can be minimized by calculating the Cartesian coordinates of the orientation data, and calculating their covariance matrix. This yields

$$I = x \cdot x^{\mathsf{T}}$$

where x is the Cartesian vector of the orientations. Orientation tensor T and the inertia tensor I are related by

$$I = E - T$$

where E denotes the unit matrix, so that

$$T = \frac{1}{n} \sum_{i=i}^{n} x_i \cdot x_i^{\mathsf{T}}$$

Value

2x2 matrix

`parse_wsm` *Numerical values to World Stress Map Quality Ranking*

Description

Assigns numeric values of the precision (sd.) of each measurement to the categorical quality ranking of the World Stress Map (A, B, C, D, E, X).

Usage

```
parse_wsm_quality(x)

quantise_wsm_quality(x)
```

Arguments

`x`	Either a string or a character/factor vector of WSM quality ranking

Value

`"numeric"`. the standard deviation of stress azimuth

Examples

```
data("pb2002")
head("pb2002")
```

plates *Plate Boundaries on the Earth*

Description

Global set of present plate boundaries on the Earth based on PB2002 model by Bird (2003). Contains the plate boundary displacement types such as inward, outward, or tangentially displacement.

Usage

```
data('plates')
```

Format

An object of class `sf`

References

Bird, P. (2003), An updated digital model of plate boundaries, *Geochem. Geophys. Geosyst.*, **4**, 1027, doi: 10.1029/2001GC000252, 3.

Examples

```
data("plates")
head("plates")
```

plot_density *Circular Density Plot*

Description

Plot the multiples of a von Mises density distribution

Usage

```
plot_density(
  x,
  kappa = NULL,
  axial = TRUE,
  n = 512L,
  norm.density = TRUE,
  ...,
  scale = 0,
  shrink = 1,
  add = TRUE,
  main = NULL,
```

```
  labels = TRUE,
  at = seq(0, 360 - 45, 45),
  cborder = TRUE,
  grid = FALSE
)
```

Arguments

x	numeric. Data to be plotted, i.e. vector containing angles (in degrees).
kappa	numeric. Concentration parameter for the von Mises distribution. Small kappa gives smooth density lines. Will be estimated using est.kappa() if not provided.
axial	Logical. Whether data are uniaxial (axial=FALSE) or biaxial (TRUE, the default).
n	integer. the number of equally spaced points at which the density is to be estimated.
norm.density	logical. Normalize the density?
...	Further graphical parameters may also be supplied as arguments.
scale	numeric. radius of plotted circle. Default is 1.1.
shrink	numeric. parameter that controls the size of the plotted function. Default is 1.
add	logical. Add to existing plot? (TRUE by default).
main	Character string specifying the title of the plot.
labels	Either a logical value indicating whether to plot labels next to the tick marks, or a vector of labels for the tick marks.
at	Optional vector of angles at which tick marks should be plotted. Set at=numeric(0) to suppress tick marks.
cborder	logical. Border of rose plot.
grid	logical. Whether a grid should be added.

Value

plot or calculated densities as numeric vector

See Also

dvm()

Other rose-plot: plot_points(), rose(), rose_geom, rose_stats()

Examples

```
# Plot density inside plot only:
rose(san_andreas$azi, grid = TRUE)
plot_density(san_andreas$azi,
  kappa = 100, col = "#51127CFF",
  add = TRUE, lwd = 3
)
```

```
# Add density curve outside of main plot:
rose(san_andreas$azi, dots = TRUE, stack = TRUE, dot_cex = 0.5, dot_pch = 21)
plot_density(san_andreas$azi,
  kappa = 100,
  scale = 1.1, shrink = 3, xpd = NA,
  col = "#51127CFF"
)
```

`plot_points` *Add Points to a Circular Plot*

Description

Add points to a plot of circular data points on the current graphics device.

Usage

```
plot_points(
  x,
  axial = TRUE,
  stack = FALSE,
  binwidth = 1,
  cex = 1,
  sep = 0.025,
  jitter_factor = 0,
  ...,
  scale = 1.1,
  add = TRUE,
  main = NULL,
  labels = TRUE,
  at = seq(0, 360 - 45, 45),
  cborder = TRUE
)
```

Arguments

`x`	Data to be plotted. A numeric vector containing angles (in degrees).
`axial`	Logical. Whether data are uniaxial (`axial=FALSE`) or biaxial (`TRUE`, the default).
`stack`	logical: if `TRUE`, points are stacked on the perimeter of the circle. Otherwise, all points are plotted on the perimeter of the circle. Default is `FALSE`.
`binwidth`	numeric. Bin width (in degrees) for the stacked dot plots. ignored when `stack==FALSE`. Is set to 1 degree by default.
`cex`	character (or symbol) expansion: a numerical vector. This works as a multiple of `par("cex")`.
`sep`	constant used to specify the distance between stacked points, if `stack==TRUE` or in the case of more than one dataset. Default is `0.025`; smaller values will create smaller spaces.

jitter_factor	numeric. Adds a small amount of random variation to the location of each points along radius that is added to scale. Jitter is ignored when stack==TRUE). If 0, no jitter is added (by default); if negative, the points fall into the circle.
...	Further graphical parameters may also be supplied as arguments.
scale	radius of plotted circle. Default is 1.1. Larger values shrink the circle, while smaller values enlarge the circle.
add	logical
main	Character string specifying the title of the plot.
labels	Either a logical value indicating whether to plot labels next to the tick marks, or a vector of labels for the tick marks.
at	Optional vector of angles at which tick marks should be plotted. Set at=numeric(0) to suppress tick marks.
cborder	logical. Border of rose plot.

Value

A list with information on the plot

See Also

Other rose-plot: plot_density(), rose(), rose_geom, rose_stats()

Examples

```
x <- rvm(100, mean = 90, k = 5)

# plot poinit without jitter
plot_points(x, add = FALSE)

# with some jitter
plot_points(x, jitter_factor = .2, add = FALSE)

# stacked dots:
plot_points(x, stack = TRUE, binwidth = 3, add = FALSE, xpd = TRUE)
```

PoR2Geo_azimuth *Azimuth Conversion From PoR to Geographical Coordinate Reference System*

Description

Conversion of PoR azimuths into geographical azimuths

Usage

```
PoR2Geo_azimuth(x, PoR, axial = TRUE)
```

Arguments

x	data.frame containing the PoR equivalent azimuths (azi.PoR), and either the geographical coordinates of the point(s) or the PoR-equivalent coordinates.
PoR	data.frame containing the geographical location of the Euler pole (lat, lon)
axial	logical. Whether the azimuth is axial (0-180) or directional (0-360).

Value

numeric vector of transformed azimuths (in degrees)

References

Stephan, T., Enkelmann, E., and Kroner, U. "Analyzing the horizontal orientation of the crustal stress adjacent to plate boundaries". *Sci Rep* 13. 15590 (2023). doi:10.1038/s41598023424332.

See Also

PoR_shmax()

Examples

```
data("nuvel1")
# North America relative to Pacific plate:
PoR <- subset(nuvel1, nuvel1$plate.rot == "na")
data("san_andreas")
san_andreas$azi.PoR <- PoR_shmax(san_andreas, PoR)

# convert back to geo CRS
PoR2Geo_azimuth(san_andreas, PoR) |> head()
```

PoR_azi *Azimuth Conversion from Geographical to PoR Coordinate Reference System*

Description

Transforms azimuths and models the direction of maximum horizontal stress σ_{Hmax} in the Euler pole (Pole of Rotation) coordinate reference system. When type of plate boundary is given, it also gives the deviation from the theoretically predicted azimuth of σ_{Hmax}, the circular distance, and the normalized χ^2 statistics.

Usage

```
PoR_azimuth(x, PoR, axial = TRUE)

PoR_shmax(x, PoR, type = c("none", "in", "out", "right", "left"), axial = TRUE)
```

Arguments

x	sf object or a data.frame containing the coordinates of the point(s) (lat, lon columns). x must contain the direction of σ_{Hmax} as column azi, its standard deviation (column unc) is optional).
PoR	data.frame or object of class euler.pole containing the geographical coordinates of the Eule pole.
axial	logical. Whether the azimuth is axial (0-180) or directional (0-360).
type	Character. Type of plate boundary (optional). Can be "out", "in", "right", or "left" for outward, inward, right-lateral, or left-lateral moving plate boundaries, respectively. If "none" (the default), only the PoR-equivalent azimuth is returned.

Details

The theoretical azimuth of σ_{Hmax} in the pole of rotation reference system is 0 (or 180), 45, 90, 135 degrees if the stress is sourced by an outward, sinistral, inward, or dextral moving plate boundary, respectively. directions of σ_{Hmax} with respect to the four plate boundary types.

Value

PoR_azimuth returns numeric vector of the transformed azimuth in degrees. PoR_shmax returns either a numeric vector of the azimuths in the transformed coordinate system (in degrees), or a "data.frame" with

azi.PoR the transformed azimuths (in degrees),

prd the predicted azimuths (in degrees),

dev the deviation between the transformed and the predicted azimuth in degrees (positive for counterclockwise deviation of observed azimuth wrt. predicted azimuth),

nchisq the Norm χ^2 test statistic, and

cdist the angular distance between the transformed and the predicted azimuth.

References

See Also

model_shmax() to compute the theoretical direction of σ_{Hmax} in the geographical reference system. deviation_shmax() to compute the deviation of the modeled direction from the observed direction of σ_{Hmax}. norm_chisq() to calculate the normalized χ^2 statistics. circular_distance() to calculate the angular distance.

Examples

```
data("nuvel1")
# North America relative to Pacific plate:
PoR <- subset(nuvel1, nuvel1$plate.rot == "na")

data("san_andreas")
res <- PoR_shmax(san_andreas, PoR, type = "right")
head(res)
```

`PoR_coordinates` *Coordinates of the Pole of Rotation Reference System*

Description

Retrieve the PoR equivalent coordinates of an object

Usage

```
PoR_coordinates(x, PoR)
```

Arguments

`x`	`sf` or `data.frame` containing lat and lon coordinates (`lat`, `lon`)
`PoR`	Pole of Rotation. `"data.frame"` or object of class `"euler.pole"` containing the geographical coordinates of the Euler pole

Value

`PoR_coordinates()` returns `data.frame` with the PoR coordinates (`lat.PoR`, `lon.PoR`).

Examples

```
data("nuvel1")
por <- subset(nuvel1, nuvel1$plate.rot == "na") # North America relative to Pacific plate
data("san_andreas")

# coordinates from sf object
san_andreas.por_sf <- PoR_coordinates(san_andreas, por)
head(san_andreas.por_sf)

# coordinates from data.frame
san_andreas.por_df <- PoR_coordinates(sf::st_drop_geometry(san_andreas), por)
head(san_andreas.por_df)
```

PoR_crs *PoR coordinate reference system*

Description

Create the reference system transformed in Euler pole coordinate

Usage

```
PoR_crs(x)
```

Arguments

x	"data.frame" or "euler.pole" object containing the geographical coordinates of the Euler pole

Details

The PoR coordinate reference system is oblique transformation of the geographical coordinate system with the Euler pole coordinates being the the translation factors.

Value

Object of class crs

See Also

sf::st_crs()

Examples

```
data("nuvel1")
por <- subset(nuvel1, nuvel1$plate.rot == "na") # North America relative to Pacific plate
PoR_crs(por)
```

PoR_distance *Distance to Pole of Rotation*

Description

Retrieve the (angular) distance to the PoR (Euler pole).

Usage

```
PoR_distance(x, PoR, FUN = orthodrome)
```

Arguments

x	sf or data.frame containing lat and lon coordinates (lat, lon)
PoR	Pole of Rotation. "data.frame" or object of class "euler.pole" containing the geographical coordinates of the Euler pole
FUN	function to calculate the great-circle distance. orthodrome(), haversine() (the default), or vincenty().

Value

numeric vector

Examples

```
data("nuvel1")
por <- subset(nuvel1, nuvel1$plate.rot == "na") # North America relative to Pacific plate
data("san_andreas")

# distance form sf object
PoR_distance(san_andreas, por) |> head()

# distance form data.frame
PoR_distance(sf::st_drop_geometry(san_andreas), por) |> head()
PoR_distance(sf::st_drop_geometry(san_andreas), por, FUN = orthodrome) |> head()
PoR_distance(sf::st_drop_geometry(san_andreas), por, FUN = vincenty) |> head()
```

PoR_map *Map of data in Pole of Rotation reference frame*

Description

Transforms the spatial data and azimuths into the PoR reference frame and shows them in a map

Usage

```
PoR_map(
  x,
  PoR,
  pb = NULL,
  type = c("none", "in", "out", "right", "left"),
  show.deviation = FALSE,
  ...
)
```

Arguments

x, pb	sf objects of the data points and the plate boundary geometries in the geographical coordinate system
PoR	Pole of Rotation. "data.frame" or object of class "euler.pole" containing the geographical coordinates of the Pole of Rotation
type	Character. Type of plate boundary (optional). Can be "out", "in", "right", or "left" for outward, inward, right-lateral, or left-lateral moving plate boundaries, respectively. If "none" (the default), only the PoR-equivalent azimuth is returned.
show.deviation	logical. Whether the data should be color-coded according to the deviation from the prediction, or according to the stress regime? Is ignored if type=='none'.
...	optional arguments passed to tectonicr.colors()

Value

plot

See Also

PoR_shmax(), axes(), tectonicr.colors()

Examples

```
data("nuvel1")
na_pa <- subset(nuvel1, nuvel1$plate.rot == "na")

data("plates")
plate_boundary <- subset(plates, plates$pair == "na-pa")

data("san_andreas")
PoR_map(san_andreas, PoR = na_pa, pb = plate_boundary, type = "right", show.deviation = TRUE)
```

PoR_stress2grid *Spatial Interpolation of SHmax in PoR Coordinate Reference System*

Description

The data is transformed into the PoR system before the interpolation. The interpolation grid is returned in geographical coordinates and azimuths.

Usage

```
PoR_stress2grid(
  x,
  PoR,
  grid = NULL,
```

```
  PoR_grid = TRUE,
  lon_range = NULL,
  lat_range = NULL,
  gridsize = 2.5,
  remove_PoR = FALSE,
  ...
)

PoR_stress2grid_stats(
  x,
  PoR,
  grid = NULL,
  PoR_grid = TRUE,
  lon_range = NULL,
  lat_range = NULL,
  gridsize = 2.5,
  remove_PoR = FALSE,
  ...
)
```

Arguments

x	sf object containing **azi** SHmax in degree **unc** Uncertainties of SHmax in degree **type** Methods used for the determination of the orientation of SHmax
PoR	Pole of Rotation. data.frame or object of class "euler.pole" containing the geographical coordinates of the Euler pole
grid	(optional) Point object of class sf.
PoR_grid	logical. Whether the grid should be generated based on the coordinate range in the PoR (TRUE, the default) CRS or the geographical CRS (FALSE). Is ignored if grid is specified.
lon_range, lat_range	(optional) numeric vector specifying the minimum and maximum longitudes and latitudes (are ignored if grid is specified).
gridsize	Numeric. Target spacing of the regular grid in decimal degree. Default is 2.5 (is ignored if grid is specified)
remove_PoR	logical. Whether PoR azimuths and coordinates will be removed from final output or not (the default.)
...	Arguments passed to stress2grid()

Details

Stress field and wavelength analysis in PoR system and back-transformed

Value

`sf` object containing

lon,lat longitude and latitude in geographical CRS (in degrees)

lon.PoR,lat.PoR longitude and latitude in PoR CRS (in degrees). Only if `remove_PoR=TRUE`

azi geographical mean SHmax in degree

azi.PoR PoR mean SHmax in degree. Only if `remove_PoR=TRUE`

sd Standard deviation of SHmax in degrees

R Search radius in km

mdr Mean distance of datapoints per search radius

N Number of data points in search radius

See Also

`stress2grid()`, `compact_grid()`

Examples

```
data("san_andreas")
data("nuvel1")
PoR <- subset(nuvel1, nuvel1$plate.rot == "na")
PoR_stress2grid(san_andreas, PoR) |> head()

## Not run:
PoR_stress2grid_stats(san_andreas, PoR, mode = TRUE) |> head()

## End(Not run)
```

`por_transformation` *Conversion between spherical PoR to geographical coordinate system*

Description

Transformation from spherical PoR to geographical coordinate system and vice versa

Usage

```
geographical_to_PoR(x, PoR)

PoR_to_geographical(x, PoR)
```

Arguments

x	Can be either a "data.frame" containing lat and lon coordinates of a point in the geographical CRS or the lat.PoR, lon.PoR) of the point in the PoR CRS, a two-column matrix containing the lat and lon coordinates, a sf object, or a raster object.
PoR	Pole of Rotation. "data.frame" containing the geographical coordinates of the Euler pole

Value

object of same type of x with the transformed coordinates. If x was a data.frame, transformed coordinates are named lat.PoR and lon.PoR for PoR CRS, or lat and lon for geographical CRS).

Examples

```
data("nuvel1")
por <- subset(nuvel1, nuvel1$plate.rot == "na") # North America relative to Pacific plate
data("san_andreas")
san_andreas.por <- geographical_to_PoR(san_andreas, por)
head(san_andreas.por)
head(PoR_to_geographical(san_andreas.por, por))
```

---

prd_err *Error of Model's Prediction*

Description

The maximum error in the model's predicted azimuth given the Pole of rotations uncertainty and distance of the data point to the pole.

Usage

```
prd_err(dist_PoR, sigma_PoR = 1)
```

Arguments

dist_PoR	Distance to Euler pole (great circle distance, in degree)
sigma_PoR	uncertainty of the position of the Pole of rotation (in degree).

Value

numeric vector. The maximum error for azimuths prediction (in degree)

References

Ramsay, J.A. Folding and fracturing of rocks. McGraw-Hill, New York, 1967.

See Also

PoR_shmax() and model_shmax() for the model's prediction, and orthodrome() for great circle distances.

Examples

```
prd_err(67, 1)

# San Andreas example:
data("nuvel1")
por <- subset(nuvel1, nuvel1$plate.rot == "na") # North America relative to Pacific plate
data("san_andreas")
d <- PoR_distance(san_andreas, por)
prd_err(d)
```

---

projected_pb_strike *Strike of the plate boundary projected on data point*

Description

The fault's strike in the PoR CRS projected on the data point along the predicted stress trajectories.

Usage

```
projected_pb_strike(x, PoR, pb, tangential = FALSE, ...)
```

Arguments

x, pb	sf objects of the data points and the plate boundary geometries in the geographical coordinate system
PoR	Pole of rotation. "data.frame" or object of class "euler.pole" containing the geographical coordinates of the Euler pole
tangential	Logical. Whether the plate boundary is a tangential boundary (TRUE) or an inward and outward boundary (FALSE, the default).
...	optional arguments passed to smoothr::densify()

Details

Useful to calculate the beta angle, i.e. the angle between SHmax direction (in PoR CRS!) and the fault's strike (in PoR CRS). The beta angle is the same in geographical and PoR coordinates.

Value

Numeric vector of the strike direction of the plate boundary (in degree)

Note

The algorithm calculates the great circle bearing between line vertices. Since transform plate boundaries represent small circle lines in the PoR system, this great-circle azimuth is only a approximation of the true (small-circle) azimuth.

Examples

```
data("nuvel1")
na_pa <- subset(nuvel1, nuvel1$plate.rot == "na")

data("plates")
plate_boundary <- subset(plates, plates$pair == "na-pa")

data("san_andreas")
res <- projected_pb_strike(
  x = san_andreas, PoR = na_pa, pb = plate_boundary, tangential = TRUE
)
head(res)
head(san_andreas$azi - res) # beta angle
```

---

quick_plot *Plotting Stress Analysis Results*

Description

Creates a set of plots including the azimuth as a function of the distance to the plate boundary, the Norm Chi-squared as a function of the distance to the plate boundary, the circular distance (and dispersion) a function of the distance to the plate boundary, a von-Mises QQ plot, and a rose diagram of the quality-weighted frequency distribution of the azimuths.

Usage

```
quick_plot(azi, distance, prd, unc = NULL, regime, width = 51)
```

Arguments

azi	numeric. Azimuth of σ_{Hmax}
distance	numeric. Distance to plate boundary
prd	numeric. the predicted direction of σ_{Hmax}
unc	numeric. Uncertainty of observed σ_{Hmax}, either a numeric vector or a number
regime	character vector. The stress regime (following the classification of the World Stress Map)
width	integer. window width (in number of observations) for moving average of the azimuths, circular dispersion, and Norm Chi-square statistics. If NULL, an optimal width will be estimated.

Details

Plot 1 shows the transformed azimuths as a function of the distance to the plate boundary. The red line indicates the rolling circular mean, stippled red lines indicate the 95% confidence interval about the mean.

Plot 2 shows the normalized χ^2 statistics as a function of the distance to the plate boundary. The red line shows the rolling χ^2 statistic.

Plot 3 shows the circular distance of the transformed azimuths to the predicted azimuth, as a function of the distance to the plate boundary. The red line shows the rolling circular dispersion about the prediction.

Plot 4 give the rose diagram of the transformed azimuths.

Value

four R base plots

See Also

PoR_shmax(), distance_from_pb(), circular_mean(), circular_dispersion(), confidence_interval_fisher(), norm_chisq(), weighted_rayleigh(), vm_qqplot()

Examples

```
data("nuvel1")
na_pa <- subset(nuvel1, nuvel1$plate.rot == "na")

data("plates")
plate_boundary <- subset(plates, plates$pair == "na-pa")

data("san_andreas")
res <- PoR_shmax(san_andreas, na_pa, "right")
d <- distance_from_pb(san_andreas, na_pa, plate_boundary, tangential = TRUE)
quick_plot(res$azi.PoR,
  distance = d, prd = res$prd, unc = san_andreas$unc,
  regime = san_andreas$regime
)
```

---

rayleigh_test *Rayleigh Test of Circular Uniformity*

Description

Performs a Rayleigh test for uniformity of circular/directional data by assessing the significance of the mean resultant length.

Usage

```
rayleigh_test(x, mu = NULL, axial = TRUE, quiet = FALSE)
```

Arguments

x	numeric vector. Values in degrees
mu	(optional) The specified or known mean direction (in degrees) in alternative hypothesis
axial	logical. Whether the data are axial, i.e. π-periodical (TRUE, the default) or directional, i.e. 2π-periodical (FALSE).
quiet	logical. Prints the test's decision.

Details

H_0: angles are randomly distributed around the circle.

H_1: angles are from non-uniformly distribution with unknown mean direction and mean resultant length (when mu is NULL. Alternatively (when mu is specified), angles are non-uniformly distributed around a specified direction.

If statistic > p.value, the null hypothesis is rejected, i.e. the length of the mean resultant differs significantly from zero, and the angles are not randomly distributed.

Value

a list with the components:

R **or** C mean resultant length or the dispersion (if mu is specified). Small values of R (large values of C) will reject uniformity. Negative values of C indicate that vectors point in opposite directions (also lead to rejection).

statistic test statistic

p.value significance level of the test statistic

Note

Although the Rayleigh test is consistent against (non-uniform) von Mises alternatives, it is not consistent against alternatives with p = 0 (in particular, distributions with antipodal symmetry, i.e. axial data). Tests of non-uniformity which are consistent against all alternatives include Kuiper's test (kuiper_test()) and Watson's U^2 test (watson_test()).

```

---

relative_rotation *Relative rotation between two rotations*

Description

Calculates the relative rotation between two rotations, i.e. the difference from rotation 1 to rotation 2.

Usage

```
relative_rotation(r1, r2)
```

Arguments

r1, r2	Objects of class "euler.pole". First rotation is r1, followed rotation r2.

Value

list. Euler axes (geographical coordinates) and Euler angles (in degrees)

References

Schaeben, H., Kroner, U. and Stephan, T. (2021). Euler Poles of Tectonic Plates. In B. S. Daza Sagar, Q. Cheng, J. McKinley and F. Agterberg (Eds.), *Encyclopedia of Mathematical Geosciences. rolling_test *Apply Rolling Functions using Circular Statistical Tests for Uniformity*

Description

A generic function for applying a function to rolling margins of an array.

Usage

```
roll_normchisq(
  obs,
  prd,
  unc = NULL,
  width = NULL,
  by.column = FALSE,
  partial = TRUE,
  fill = NA,
  ...
)

roll_rayleigh(
  obs,
  prd,
  unc = NULL,
  width = NULL,
  by.column = FALSE,
  partial = TRUE,
  fill = NA,
  ...
)
```

```
roll_dispersion(
  x,
  y,
  w = NULL,
  w.y = NULL,
  width = NULL,
  by.column = FALSE,
  partial = TRUE,
  fill = NA,
  ...
)

roll_confidence(
  x,
  conf.level = 0.95,
  w = NULL,
  axial = TRUE,
  width = NULL,
  by.column = FALSE,
  partial = TRUE,
  fill = NA,
  ...
)

roll_dispersion_CI(
  x,
  y,
  w = NULL,
  w.y = NULL,
  R,
  conf.level = 0.95,
  width = NULL,
  by.column = FALSE,
  partial = TRUE,
  fill = NA,
  ...
)

roll_dispersion_sde(
  x,
  y,
  w = NULL,
  w.y = NULL,
  R,
  conf.level = 0.95,
  width = NULL,
  by.column = FALSE,
```

```
  partial = TRUE,
  fill = NA,
  ...
)
```

Arguments

obs	Numeric vector containing the observed azimuth of σ_{Hmax}, same length as prd
prd	Numeric vector containing the modeled azimuths of σ_{Hmax}, i.e. the return object from model_shmax()
unc	Uncertainty of observed σ_{Hmax}, either a numeric vector or a number
width	integer specifying the window width (in numbers of observations) which is aligned to the original sample according to the align argument. If NULL, an optimal width is estimated.
by.column	logical. If TRUE, FUN is applied to each column separately.
partial	logical or numeric. If FALSE then FUN is only applied when all indexes of the rolling window are within the observed time range. If TRUE (default), then the subset of indexes that are in range are passed to FUN. A numeric argument to partial can be used to determine the minimal window size for partial computations. See below for more details.
fill	a three-component vector or list (recycled otherwise) providing filling values at the left/within/to the right of the data range. See the fill argument of zoo::na.fill() for details
...	optional arguments passed to zoo::rollapply()
x, y	numeric. Directions in degrees
w, w.y	(optional) Weights of x and y, respectively. A vector of positive numbers and of the same length as x.
conf.level	Level of confidence: $(1-\alpha\%)/100$. (0.95 by default).
axial	logical. Whether the data are axial, i.e. pi-periodical (TRUE, the default) or directional, i.e. 2π-periodical (FALSE).
R	The number of bootstrap replicates.

Value

numeric vector with the test statistic of the rolling test. roll_dispersion_CI returns a 2-column matrix with the lower and the upper confidence limits

Note

If the rolling functions are applied to values that are a function of distance it is recommended to sort the values first.

Examples

```
data("plates")
plate_boundary <- subset(plates, plates$pair == "na-pa")
data("san_andreas")
PoR <- subset(nuvel1, nuvel1$plate.rot == "na")
distance <- distance_from_pb(
  x = san_andreas,
  PoR = PoR,
  pb = plate_boundary,
  tangential = TRUE
)
dat <- san_andreas[order(distance), ]
dat.PoR <- PoR_shmax(san_andreas, PoR, "right")
roll_normchisq(dat.PoR$azi.PoR, 135, dat$unc) |> head()
roll_rayleigh(dat.PoR$azi.PoR, prd = 135, unc = dat$unc) |> head()
roll_dispersion(dat.PoR$azi.PoR, y = 135, w = 1 / dat$unc) |> head()
roll_confidence(dat.PoR$azi.PoR, w = 1 / dat$unc) |> head()

roll_dispersion_CI(dat.PoR$azi.PoR, y = 135, w = 1 / dat$unc, R = 10) |> head()
```

---

roll_circstats *Apply Rolling Functions using Circular Statistics*

Description

A generic function for applying a function to rolling margins of an array.

Usage

```
roll_circstats(
  x,
  w = NULL,
  FUN,
  axial = TRUE,
  na.rm = TRUE,
  width = NULL,
  by.column = FALSE,
  partial = TRUE,
  fill = NA,
  ...
)
```

Arguments

x	numeric vector. Values in degrees.
w	(optional) Weights. A vector of positive numbers and of the same length as x.
FUN	the function to be applied

axial	logical. Whether the data are axial, i.e. pi-periodical (TRUE, the default) or directional, i.e. 2π-periodical (FALSE).
na.rm	logical value indicating whether NA values in x should be stripped before the computation proceeds.
width	integer specifying the window width (in numbers of observations) which is aligned to the original sample according to the align argument. If NULL, an optimal width is calculated.
by.column	logical. If TRUE, FUN is applied to each column separately.
partial	logical or numeric. If FALSE then FUN is only applied when all indexes of the rolling window are within the observed time range. If TRUE (default), then the subset of indexes that are in range are passed to FUN. A numeric argument to partial can be used to determine the minimal window size for partial computations. See below for more details.
fill	a three-component vector or list (recycled otherwise) providing filling values at the left/within/to the right of the data range. See the fill argument of zoo::na.fill() for details
...	optional arguments passed to zoo::rollapply()

Value

numeric vector with the results of the rolling function.

Note

If the rolling statistics are applied to values that are a function of distance it is recommended to sort the values first.

Examples

```
data("plates")
plate_boundary <- subset(plates, plates$pair == "na-pa")
data("san_andreas")
PoR <- subset(nuvel1, nuvel1$plate.rot == "na")
distance <- distance_from_pb(
  x = san_andreas,
  PoR = PoR,
  pb = plate_boundary,
  tangential = TRUE
)
dat <- san_andreas[order(distance), ]
roll_circstats(dat$azi, w = 1 / dat$unc, circular_mean, width = 51) |> head()
```

rose *Rose Diagram*

Description

Plots a rose diagram (rose of directions), the analogue of a histogram or density plot for angular data.

Usage

```
rose(
  x,
  weights = NULL,
  binwidth = NULL,
  bins = NULL,
  axial = TRUE,
  equal_area = TRUE,
  muci = TRUE,
  round_binwidth = 0,
  mtext = "N",
  main = NULL,
  sub = NULL,
  at = seq(0, 360 - 45, 45),
  cborder = TRUE,
  labels = TRUE,
  col = "grey",
  dots = FALSE,
  dot_pch = 1,
  dot_cex = 1,
  dot_col = "slategrey",
  stack = FALSE,
  jitter_factor = 0,
  grid = FALSE,
  grid.lines = seq(0, 135, 45),
  grid.circles = seq(0.2, 1, 0.2),
  add = FALSE,
  ...
)
```

Arguments

x	Data to be plotted. A numeric vector containing angles (in degrees).
weights	Optional vector of numeric weights associated with x.
binwidth	The width of the bins (in degrees).
bins	number of arcs to partition the circle width. Overridden by binwidth.
axial	Logical. Whether data are uniaxial (axial=FALSE) or biaxial (TRUE, the default).

equal_area	Logical. Whether the radii of the bins are proportional to the frequencies (equal_area=FALSE, i.e. equal-angle) or proportional to the square-root of the frequencies (equal_area=TRUE, the default).
muci	logical. Whether the mean and its 95% CI are added to the plot or not.
round_binwidth	integer. Number of decimal places of bin width (0 by default).
mtext	character. String to be drawn at the top margin of the plot ("N" by default)
main, sub	Character string specifying the title and subtitle of the plot. If sub = NULL, it will show the bin width.
at	Optional vector of angles at which tick marks should be plotted. Set at=numeric(0) to suppress tick marks.
cborder	logical. Border of rose plot.
labels	Either a logical value indicating whether to plot labels next to the tick marks, or a vector of labels for the tick marks.
col	fill color of bins
dots	logical. Whether a circular dot plot should be added (FALSE is the default).
dot_cex, dot_pch, dot_col	Plotting arguments for circular dot plot
stack	logical. Groups and stacks the dots if TRUE. Default is FALSE.
jitter_factor	Add a small amount of noise to the angles' radius that is added to scale. Jitter is ignored when stack==TRUE). If 0, no jitter is added (by default); if negative, the points fall into the circle.
grid	logical. Whether to add a grid. Default is FALSE.
grid.lines, grid.circles	numeric. Adds a sequence of straight grid lines and circles based on angles and radii, respectively. Ignored when grid=FALSE
add	logical.
...	Additional arguments passed to spatstat.explore::rose().

Value

A window (class "owin") containing the plotted region or a list of the calculated frequencies.

Note

If bins and binwidth are NULL, an optimal bin width will be calculated using Scott (1979):

$$w_b = \frac{R}{n^{\frac{1}{3}}}$$

with n being the length of x, and the range R being either 180 or 360 degree for axial or directional data, respectively.

If "axial" == TRUE, the binwidth is adjusted to guarantee symmetrical fans.

Examples

```
x <- rvm(100, mean = 90, k = 5)
rose(x, axial = FALSE, border = TRUE, grid = TRUE)

data("san_andreas")
rose(san_andreas$azi, main = "equal area")
rose(san_andreas$azi, equal_area = FALSE, main = "equal angle")

# weighted frequencies:
rose(san_andreas$azi, weights = 1 / san_andreas$unc, main = "weighted")

# add dots:
rose(san_andreas$azi, dots = TRUE, main = "dot plot", jitter = .2)

# stack dots:
rose(san_andreas$azi,
  dots = TRUE, stack = TRUE, dot_cex = 0.5, dot_pch = 21,
  main = "stacked dot plot"
)
```

`rose_geom` *Direction Lines and Fans in Circular Diagram*

Description

Direction Lines and Fans in Circular Diagram

Usage

```
rose_line(x, radius = 1, axial = TRUE, add = TRUE, ...)

rose_fan(x, d, radius = 1, axial = TRUE, add = TRUE, ...)
```

Arguments

`x`	angles in degrees
`radius`	of the plotted circle
`axial`	Logical. Whether `x` are uniaxial (`axial=FALSE`) or biaxial (`TRUE`, the default).
`add`	logical. Add to existing plot?
`...`	optional arguments passed to `graphics::segments()` or `graphics::polygon()`
`d`	width of a fan (in degrees)

Value

No return value, called for side effects

See Also

Other rose-plot: `plot_density()`, `plot_points()`, `rose()`, `rose_stats()`

Examples

```
angles <- c(0, 10, 45)
radius <- c(.7, 1, .2)
lwd <- c(2, 1, .75)
col <- c(1, 2, 3)
rose_line(angles, radius = radius, axial = FALSE, add = FALSE, lwd = lwd, col = col)
```

---

rose_stats *Show Average Direction and Spread in Rose Diagram*

Description

Adds the average direction (and its spread) to an existing rose diagram.

Usage

```
rose_stats(
  x,
  weights = NULL,
  axial = TRUE,
  avg = c("mean", "median", "sample_median"),
  spread = c("CI", "fisher", "sd", "IQR", "mdev"),
  avg.col = "#B63679FF",
  avg.lty = 2,
  avg.lwd = 1.5,
  spread.col = ggplot2::alpha("#B63679FF", 0.2),
  spread.border = FALSE,
  spread.lty = NULL,
  spread.lwd = NULL,
  add = TRUE,
  ...
)
```

Arguments

x	Data to be plotted. A numeric vector containing angles (in degrees).
weights	Optional vector of numeric weights associated with x.
axial	Logical. Whether data are uniaxial (`axial=FALSE`) or biaxial (`TRUE`, the default).
avg	character. The average estimate for x. Either the circular mean (`"mean"`, the default), the circular Quasi Median (`"median"`), or the sample median (`"sample_median"`).

spread	character. The measure of spread to be plotted as a fan. Either Batchelet's 95% confidence interval by ("CI", the default), Fisher's 95% confidence interval ("fisher"), the circular standard deviation ("sd"), the Quasi interquartile range on the circle ("IQR"), or the sample median deviation ("mdev"). NULL if no fan should be drawn.
avg.col	color for the average line
avg.lty	line type of the average line
avg.lwd	line width of the average line
spread.col	color of the spread fan
spread.border	logical. Whether to draw a border of the fan or not.
spread.lty	line type of the spread fan's border
spread.lwd	line width of the spread fan's border
add	logical.
...	optional arguments to circular_plot() if add is FALSE.

Value

plot or a two-element vector containing the calculated average and spread when assigned.

See Also

circular_mean(), circular_median(), circular_sample_median(), confidence_interval(), confidence_interval_fisher(), circular_sd(), circular_IQR(), circular_sample_median_deviation() for statistical parameters.

Other rose-plot: plot_density(), plot_points(), rose(), rose_geom

Examples

```
data("san_andreas")
rose(san_andreas$azi, weights = 1 / san_andreas$unc, muci = FALSE)
rose_stats(san_andreas$azi, weights = 1 / san_andreas$unc, avg = "sample_median", spread = "mdev")
```

---

sample_dispersion *Sample circular dispersion*

Description

Alternative versions of variance, dispersion a distance (Mardia and Jupp, 1999; pp. 19-20). These alternative dispersion has a minimum at the sample median.

Usage

```
sample_circular_variance(x, w = NULL, axial = TRUE)

sample_circular_distance(x, y, axial = TRUE, na.rm = TRUE)

sample_circular_dispersion(
  x,
  y = NULL,
  w = NULL,
  w.y = NULL,
  axial = TRUE,
  na.rm = TRUE
)
```

Arguments

x, y	vectors of numeric values in degrees. length(y) is either 1 or length(x)
w, w.y	(optional) Weights. A vector of positive numbers and of the same length as x. w.y is the (optional) weight of y.
axial	logical. Whether the data are axial, i.e. pi-periodical (TRUE, the default) or directional, i.e. 2π-periodical (FALSE).
na.rm	logical. Whether NA values in x should be stripped before the computation proceeds.

References

N.I. Fisher (1993) Statistical Analysis of Circular Data, Cambridge University Press.

Mardia, K.V., and Jupp, P.E (1999). Directional Statistics, Wiley Series in Probability and Statistics. John Wiley & Sons, Inc., Hoboken, NJ, USA. doi:10.1002/9780470316979

Examples

```
a <- c(0, 2, 359, 6, 354)
sample_circular_distance(a, 10) # distance to single value

b <- a + 90
sample_circular_distance(a, b) # distance to multiple values

data("nuvel1")
PoR <- subset(nuvel1, nuvel1$plate.rot == "na")
sa.por <- PoR_shmax(san_andreas, PoR, "right")
sample_circular_variance(sa.por$azi.PoR)
sample_circular_dispersion(sa.por$azi.PoR, y = 135)
sample_circular_dispersion(sa.por$azi.PoR, y = 135, w = weighting(san_andreas$unc))
```

`sample_median` *Sample Circular Median and Deviation*

Description

Sample median direction for a vector of circular data

Usage

```
circular_sample_median(x, axial = TRUE, na.rm = TRUE)

circular_sample_median_deviation(x, axial = TRUE, na.rm = TRUE)
```

Arguments

`x`	numeric vector. Values in degrees.
`axial`	logical. Whether the data are axial, i.e. pi-periodical (`TRUE`, the default) or directional, i.e. 2π-periodical (`FALSE`).
`na.rm`	logical value indicating whether `NA` values in `x` should be stripped before the computation proceeds.

Value

numeric

References

N.I. Fisher (1993) Statistical Analysis of Circular Data, Cambridge University Press.

Examples

```
set.seed(1)
x <- rvm(n = 100, mean = 0, kappa = 10)
circular_sample_median(x)
circular_sample_median_deviation(x)

data("san_andreas")
circular_sample_median(san_andreas$azi)
circular_sample_median_deviation(san_andreas$azi)
```

second_central_moment *Second Central Momentum*

Description

Measures the skewness (a measure of the asymmetry of the probability distribution) and the kurtosis (measure of the "tailedness" of the probability distribution). Standardized versions are the skewness and kurtosis normalized by the mean resultant length (Mardia 1972).

Usage

```
second_central_moment(x, w = NULL, axial = TRUE, na.rm = FALSE)
```

Arguments

x	numeric vector. Values in degrees.
w	(optional) Weights. A vector of positive numbers and of the same length as x.
axial	logical. Whether the data are axial, i.e. pi-periodical (TRUE, the default) or directional, i.e. 2π-periodical (FALSE).
na.rm	logical value indicating whether NA values in x should be stripped before the computation proceeds.

Details

Negative values of skewness indicate skewed data in counterclockwise direction.

Large kurtosis values indicate tailed, values close to 0 indicate packed data.

Value

list containing

skewness second central sine momentum, i.e. the skewness

std_skewness standardized skewness

kurtosis second central cosine momentum, i.e. the kurtosis

std_kurtosis standardized kurtosis

Examples

```
data("nuvel1")
PoR <- subset(nuvel1, nuvel1$plate.rot == "na")
sa.por <- PoR_shmax(san_andreas, PoR, "right")
second_central_moment(sa.por$azi.PoR)
second_central_moment(sa.por$azi.PoR, w = weighting(san_andreas$unc))
```

shortest_distance_to_line *Shortest distance between pairs of geometries*

Description

The shortest Great Circle distance between pairs of geometries

Usage

```
shortest_distance_to_line(x, line, ellipsoidal = FALSE)
```

Arguments

x, line	objects of class sfg, sfc or sf
ellipsoidal	Logical. Whether the distance is calculated using spherical distances (sf::st_distance()) or ellipsoidal distances (lwgeom::st_geod_distance()).

Value

numeric. Shortest distance in meters

Examples

```
plate_boundary <- subset(plates, plates$pair == "na-pa")
shortest_distance_to_line(san_andreas, plate_boundary) |>
  head()
```

spec_atan *Quadrant-specific inverse of the tangent*

Description

Returns the quadrant specific inverse of the tangent

Usage

```
atan2_spec(x, y)

atan2d_spec(x, y)
```

Arguments

x, y	dividend and divisor that comprise the sum of sines and cosines, respectively.

Value

numeric.

References

Jammalamadaka, S. Rao, and Ambar Sengupta (2001). Topics in circular statistics. Vol. 5. world scientific.

`spherical_angle` *Angle along great circle on spherical surface*

Description

Smallest angle between two points on the surface of a sphere, measured along the surface of the sphere

Usage

```
orthodrome(lat1, lon1, lat2, lon2)

haversine(lat1, lon1, lat2, lon2)

vincenty(lat1, lon1, lat2, lon2)
```

Arguments

`lat1`, `lat2`	numeric vector. latitudes of point 1 and 2 (in radians)
`lon1`, `lon2`	numeric vector. longitudes of point 1 and 2 (in radians)

Details

`"orthodrome"` based on the spherical law of cosines

`"haversine"` uses haversine formula that is optimized for 64-bit floating-point numbers

`"vincenty"` uses Vincenty formula for an ellipsoid with equal major and minor axes

Value

numeric. Angle in radians

```

---

stress2grid *Spatial Interpolation of SHmax*

Description

Stress field interpolation and wavelength analysis using a kernel (weighted) mean/median and standard deviation/IQR of stress data. Parameters can be adjusted to have inverse-distance-weighting (IDW) or nearest-neighbor interpolations (NN).

Usage

```
stress2grid(
  x,
  stat = c("mean", "median", "tensor"),
  grid = NULL,
  lon_range = NULL,
  lat_range = NULL,
  gridsize = 2,
  min_data = 3L,
  max_data = Inf,
  max_sd = Inf,
  threshold = deprecated(),
  min_dist_threshold = 200,
  arte_thres = deprecated(),
  method_weighting = FALSE,
  quality_weighting = TRUE,
  dist_weighting = c("inverse", "linear", "none"),
  idp = 1,
  qp = 1,
  mp = 1,
  dist_threshold = 0.1,
  R_range = seq(50, 1000, 50),
  ...
)

stress2grid_stats(
```

```
  x,
  grid = NULL,
  lon_range = NULL,
  lat_range = NULL,
  gridsize = 2,
  min_data = 4L,
  max_data = Inf,
  threshold = deprecated(),
  min_dist_threshold = 200,
  arte_thres = deprecated(),
  method_weighting = FALSE,
  quality_weighting = TRUE,
  dist_weighting = c("inverse", "linear", "none"),
  idp = 1,
  qp = 1,
  mp = 1,
  dist_threshold = 0.1,
  R_range = seq(50, 1000, 50),
  mode = FALSE,
  kappa = 10,
  ...
)
```

Arguments

`x`	`sf` object containing **azi** SHmax in degree **unc** (optional) Uncertainties of SHmax in degree **type** (optional) Methods used for the determination of the direction of SHmax
`stat`	whether the direction of interpolated SHmax is based on the circular mean and standard deviation (`"mean"`, the default), the quasi-circular median and quasi-interquartile range (`"median"`), or the orientation tensor based principal direction and dispersion ("tensor").
`grid`	(optional) Point object of class `sf`.
`lon_range, lat_range`	(optional) numeric vector specifying the minimum and maximum longitudes and latitudes (ignored if `grid` is specified).
`gridsize`	numeric. Target spacing of the regular grid in decimal degree. Default is `2.5`. (is ignored if `grid` is specified)
`min_data`	integer. If the number of observations within distance `R_range` is less than `min_data`, a missing value `NA` will be generated. Default is 3 for `stress2grid()` and 4 for `stress2grid_stats()`.
`max_data`	integer. The number of nearest observations that should be used for prediction, where "nearest" is defined in terms of the space of the spatial locations. Default is `Inf`.
`max_sd`	numeric. Threshold for deviation of direction in degrees; if exceeds, missing values will be generated.

`threshold` **[Deprecated]** is no longer supported; use `max_sd` instead.

`min_dist_threshold`
: numeric. Distance threshold for smallest distance of the prediction location to the next observation location. Default is `200` km.

`arte_thres` **[Deprecated]** is no longer supported; use `min_dist_threshold` instead.

`method_weighting`
: logical. If a method weighting should be applied: Default is `FALSE`. If `FALSE`, overwrites `mp`.

`quality_weighting`
: logical. If a quality weighting should be applied: Default is `TRUE`. If `FALSE`, overwrites `qp`.

`dist_weighting` Distance weighting method which should be used. One of `"none"`, `"linear"`, or `"inverse"` (the default).

`idp, qp, mp` numeric. The weighting power of inverse distance, quality and method (the higher the value, the more weight). Default is `1`. When set to `0`, no weighting is applied. Only effective when `dist_weighting=="inverse"`.

`dist_threshold` numeric. Distance weight to prevent overweight of data nearby (0 to 1). Default is `0.1`

`R_range` numeric value or vector specifying the kernel half-width(s) search radii, i.e. the maximum distance from the prediction location to be used for prediction (in km). Default is `seq(50, 1000, 50)`. If combined with `max_data`, both criteria apply.

`...` (optional) arguments to `dist_greatcircle()`

`mode` logical. Should the circular mode be included in the statistical summary (slow)?

`kappa` numeric. von Mises distribution concentration parameter used for the circular mode. Will be estimated using `est.kappa()` if not provided.

Details

`stress2grid()` is originally based on the MATLAB script "stress2grid" by Ziegler and Heidbach (2019): https://github.com/MorZieg/Stress2Grid. The tectonicr version has been significantly modified to provide better performance and more flexibility.

`stress2grid_stats()` is based on `stress2grid()` but calculates circular summary statistics (see `circular_summary()`).

Value

`sf` object containing

lon,lat longitude and latitude in degrees

azi Circular mean od median SHmax in degree

sd Circular standard deviation or Quasi-IQR on the Circle of SHmax in degrees

R Search radius in km

mdr Mean distance between grid point and datapoints per search radius

N Number of data points in search radius

When `stress2grid_stats()`, `azi` and `sd` are replaced by the output of `circular_summary()`.

stress2grid_stats(san_andreas) |> head()

## End(Not run)
```

---

stress_analysis *Quick analysis of a stress data set*

Description

Returns the converted azimuths, distances to the plate boundary, statistics of the model, and some plots.

Usage

```
stress_analysis(
  x,
  PoR,
  type = c("none", "in", "out", "right", "left"),
  pb,
  plot = TRUE,
  ...
)
```

Arguments

x	data.frame or sf object containing the coordinates of the point(s) (lat, lon), the direction of σ_{Hmax} azi and its standard deviation unc (optional)
PoR	Pole of Rotation. data.frame or object of class "euler.pole" containing the geographical coordinates of the Euler pole
type	Character. Type of plate boundary (optional). Can be "out", "in", "right", or "left" for outward, inward, right-lateral, or left-lateral moving plate boundaries, respectively. If "none" (the default), only the PoR-equivalent azimuth is returned.
pb	(optional) sf object of the plate boundary geometries in the geographical coordinate system
plot	(logical). Whether to produce a plot additional to output.
...	optional arguments to distance_from_pb()

Value

list containing the following values:

- results data.frame showing the the coordinate and azimuth conversions (lat.PoR, lon.PoR, and azi.PoR), the predicted azimuths (prd), deviation angle from predicted (dev), circular distance (cdist), misfit to predicted stress direction (nchisq) and, if given, distance to tested plate boundary (distance)
- stats array with circular (weighted) mean, circular standard deviation, circular variance, circular median, skewness, kurtosis, the 95% confidence angle, circular dispersion, and the normalized Chi-squared test statistic
- test list containing the test results of the (weighted) Rayleigh test against the uniform distribution about the predicted orientation.

data("plates")
plate_boundary <- subset(plates, plates$pair == "na-pa")

data("san_andreas")
stress_analysis(san_andreas, na_pa, type = "right", plate_boundary, plot = TRUE)
```

stress_colors *Color palette for stress regime*

Description

Color palette for stress regime

Usage

```
stress_colors()
```

Value

function

Examples

```
stress_colors()
```

stress_data *Example crustal stress dataset*

Description

Subsets of the World Stress Map (WSM) compilation of information on the crustal present-day stress field (Version 1.1. 2019).

Usage

```
data('san_andreas')

data('tibet')

data('iceland')
```

Format

A `sf` object / `data.frame` with 10 columns. Each row represents a different in-situ stress measurement:

id Measurement identifier

lat Latitude in degrees

lon Longitude in degrees

azi SHmax azimuth in degrees

unc Measurement standard deviation (in degrees)

type Type of measurement

depth Depth in km

quality WSM quality rank

regime Stress regime

An object of class `sf` (inherits from `data.frame`) with 1126 rows and 10 columns.

An object of class `sf` (inherits from `data.frame`) with 1165 rows and 10 columns.

An object of class `sf` (inherits from `data.frame`) with 490 rows and 10 columns.

Details

`'san_andreas"` contains 407 stress data adjacent to the San Andreas Fault to be tested against a tangentially displaced plate boundary.

`"tibet"` contains 947 stress data from the Himalaya and Tibetan plateau to be tested against an inward-moving displaced plate boundary.

`'iceland` contains 201 stress data from Iceland to be tested against a outward-moving displaced plate boundary.

```

stress_paths *Theoretical Plate Tectonic Stress Paths*

Description

Construct σ_{Hmax} lines that are following small circles, great circles, or loxodromes of an Euler pole for the relative plate motion.

Usage

```
eulerpole_paths(x, type = c("sc", "gc", "ld"), n = 10, angle = 45, cw)

eulerpole_smallcircles(x, n = 10)

eulerpole_greatcircles(x, n = 10)

eulerpole_loxodromes(x, n = 10, angle = 45, cw)
```

Arguments

x	Either an object of class "euler.pole" or "data.frame" containing coordinates of Euler pole in lat, lon, and rotation angle (optional).
type	Character string specifying the type of curves to export. Either "sm" for small circles (default), "gc" for great circles, or "ld" for loxodromes.
n	Number of equally spaced curves; n = 10 by default (angular distance between curves: 180 / n)
angle	Direction of loxodromes; angle = 45 by default.
cw	logical. Sense of loxodromes: TRUE for clockwise loxodromes (left-lateral displaced plate boundaries). FALSE for counterclockwise loxodromes (right-lateral displaced plate boundaries).

Details

Maximum horizontal stress can be aligned to three types of curves related to relative plate motion:

Small circles Lines that have a constant distance to the Euler pole. If x contains angle, output additionally gives absolute velocity on small circle (degree/Myr -> km/Myr).

Great circles Paths of the shortest distance between the Euler pole and its antipodal position.

Loxodromes Lines of constant bearing, i.e. curves cutting small circles at a constant angle.

Value

sf object

Author(s)

Tobias Stephan

Examples

```
data("nuvel1")
por <- subset(nuvel1, nuvel1$plate.rot == "na") # North America relative to
# Pacific plate

eulerpole_smallcircles(por)
eulerpole_greatcircles(por)
eulerpole_loxodromes(x = por, angle = 45, n = 10, cw = FALSE)
eulerpole_loxodromes(x = por, angle = 30, cw = TRUE)
eulerpole_smallcircles(data.frame(lat = 30, lon = 10))
```

---

superimposed_shmax *SHmax direction resulting from multiple plate boundaries*

Description

Calculates a σ_{Hmax} direction at given coordinates, sourced by multiple plate boundaries. This first-order approximation is the circular mean of the superimposed theoretical directions, weighted by the rotation rates of the underlying PoRs.

Usage

```
superimposed_shmax(df, PoRs, types, absolute = TRUE, PoR_weighting = NULL)
```

Arguments

df	data.frame containing the coordinates of the point(s) (lat, lon), and the direction of σ_{Hmax} azi (in degrees)
PoRs	multirow data.frame or "euler.pole" object that must contain lat, lon and angle
types	character vector with length equal to number of rows in PoRs. Type of plate boundary. Must be "out", "in", "right", or "left" for outward, inward, right-lateral, or left-lateral moving plate boundaries, respectively.
absolute	logical. Whether the resultant azimuth should be weighted using the absolute rotation at the points or the angular rotation of the PoRs.
PoR_weighting	(optional) numeric vector with length equal to number of rows in PoRs. Extra weightings for the used PoRs.

Value

two column vector. azi is the resultant azimuth in degrees / geographical CRS), R is the resultant length.

See Also

model_shmax()

superimposed_shmax_PB() for considering distances to plate boundaries

Examples

```
data(san_andreas)
data(nuvel1)
pors <- subset(nuvel1, plate.rot %in% c("eu", "na"))
res <- superimposed_shmax(san_andreas, pors, types = c("in", "right"), PoR_weighting = c(2, 1))
head(res)
```

`superimposed_shmax_PB` *SHmax direction resulting from multiple plate boundaries considering distance to plate boundaries*

Description

Calculates a σ_{Hmax} direction at given coordinates, sourced by multiple plate boundaries. This first-order approximation is the circular mean of the superimposed theoretical directions, weighted by the rotation rates of the underlying PoRs, the inverse distance to the plate boundaries, and the type of plate boundary.

Usage

```
superimposed_shmax_PB(
  x,
  pbs,
  model,
  rotation_weighting = TRUE,
 type_weights = c(divergent = 1, convergent = 3, transform_L = 2, transform_R = 2),
  idp = 1
)
```

Arguments

`x`	grid. An object of `sf`, `sfc` or 2-column matrix
`pbs`	plate boundaries. `sf` object
`model`	`data.frame` containing the Euler pole parameters. See `equivalent_rotation()` for details.
`rotation_weighting`	logical.
`type_weights`	named vector.
`idp`	numeric. Weighting power of inverse distance. The higher the number, the less impact far-distant boundaries have. When set to `0`, no weighting is applied.

Value

two-column matrix. `azi` is the resultant azimuth (in degrees), `R` is the resultant length.

tectonicr.colors *Colors for input variables*

Description

assigns colors to continuous or categorical values for plotting

Usage

```
tectonicr.colors(
  x,
  n = 10,
  pal = NULL,
  categorical = FALSE,
  na.value = "grey",
  ...
)
```

Arguments

x	values for color assignment
n	integer. number of colors for continuous colors (i.e. 'categorical = FALSE").
pal	either a named vector specifying the colors for categorical values, or a color function. If NULL, default colors are RColorBrewer::brewer.pal() (categorical = TRUE) and viridis::viridis() (categorical = FALSE).
categorical	logical.
na.value	color for NA values (categorical).
...	optional arguments passed to palette function

Value

named color vector

Examples

```
val1 <- c("N", "S", "T", "T", NA)
tectonicr.colors(val1, categorical = TRUE)
tectonicr.colors(val1, pal = stress_colors(), categorical = TRUE)

val2 <- runif(10)
tectonicr.colors(val2, n = 5)
```

---

vcross *Vector cross product*

Description

Vector or cross product

Usage

```
vcross(x, y)
```

Arguments

x, y	numeric vectors of length 3

Value

numeric vector of length 3

Examples

```
vcross(c(1, 2, 3), c(4, 5, 6))
```

---

vm_qqplot *von Mises Quantile-Quantile Plot*

Description

Produces a Q-Q plot of the data against a specified von Mises distribution to graphically assess the goodness of fit of the model.

Usage

```
vm_qqplot(
  x,
  w = NULL,
  axial = TRUE,
  mean = NULL,
  kappa = NULL,
  xlab = "von Mises quantile function",
  ylab = "Empirical quantile function",
  main = "von Mises Q-Q Plot",
  col = "#B63679FF",
  add_line = TRUE,
  ...
)
```

Arguments

x	numeric. Angles in degrees
w	numeric. optional weightings for x to estimate mean and kappa.
axial	Logical. Whether data are uniaxial (axial=FALSE)
mean	numeric. Circular mean of the von Mises distribution. If NULL, it will be estimated from x.
kappa	numeric. Concentration parameter of the von Mises distribution. If NULL, it will be estimated from x.
xlab, ylab, main	plot labels.
col	color for the dots.
add_line	logical. Whether to connect the points by straight lines?
...	graphical parameters

Value

plot

Examples

```
# von Mises distribution
x_vm <- rvm(100, mean = 0, kappa = 4)
vm_qqplot(x_vm, axial = FALSE, pch = 20)

# uniform distribution
x_unif <- runif(100, 0, 360)
vm_qqplot(x_unif, axial = FALSE, pch = 20)
```

vonmises *The von Mises Distribution*

Description

Density, probability distribution function, quantiles, and random generation for the circular normal distribution with mean and kappa.

Usage

```
rvm(n, mean, kappa)

dvm(theta, mean, kappa, log = FALSE, axial = FALSE)

pvm(theta, mean, kappa, from = NULL, tol = 1e-20)

qvm(p, mean = 0, kappa, from = NULL, tol = .Machine$double.eps^(0.6), ...)
```

Arguments

n	integer. Number of observations in degrees
mean	numeric. Mean angle in degrees
kappa	numeric. Concentration parameter in the range (0, Inf]
theta	numeric. Angular value in degrees
log	logical. If TRUE, probabilities p are given as log(p).
axial	logical. Whether the data are axial, i.e. π-periodical (TRUE, the default) or directional, i.e. 2π-periodical (FALSE).
from	if NULL is set to $\mu - \pi$. This is the value from which the pvm and qvm are evaluated. in degrees.
tol	numeric. The precision in evaluating the distribution function or the quantile.
p	numeric. Vector of probabilities with values in $[0, 1]$.
...	parameters passed to stats::integrate().

Value

dvm gives the density, pvm gives the probability of the von Mises distribution function, rvm generates random deviates (in degrees), and qvm provides quantiles (in degrees).

Examples

```
set.seed(1)
x <- rvm(5, mean = 90, kappa = 2)

dvm(x, mean = 90, kappa = 2)
dvm(x, mean = 90, kappa = 2, axial = TRUE)
```

```
pvm(x, mean = 90, kappa = 2)
qvm(c(.25, .5, .75), mean = 90, kappa = 2)
```

`watson_test` *Watson's U^2 Test of Circular Uniformity*

Description

Watson's test statistic is a rotation-invariant Cramer - von Mises test

Usage

```
watson_test(
  x,
  alpha = 0,
  dist = c("uniform", "vonmises"),
  axial = TRUE,
  mu = NULL,
  quiet = FALSE
)
```

Arguments

`x`	numeric vector. Values in degrees
`alpha`	Significance level of the test. Valid levels are `0.01`, `0.05`, and `0.1`. This argument may be omitted (`NULL`, the default), in which case, a range for the p-value will be returned.
`dist`	Distribution to test for. The default, `"uniform"`, is the uniform distribution. `"vonmises"` tests the von Mises distribution.
`axial`	logical. Whether the data are axial, i.e. π-periodical (`TRUE`, the default) or circular, i.e. 2π-periodical (`FALSE`).
`mu`	(optional) The specified mean direction (in degrees) in alternative hypothesis
`quiet`	logical. Prints the test's decision.

Details

If `statistic > p.value`, the null hypothesis is rejected. If not, randomness (uniform distribution) cannot be excluded.

Value

list containing the test statistic `statistic` and the significance level `p.value`.

weighted_rayleigh *Weighted Goodness-of-fit Test for Circular Data*

Description

Weighted version of the Rayleigh test (or V0-test) for uniformity against a distribution with a priori expected von Mises concentration.

Usage

```
weighted_rayleigh(x, mu = NULL, w = NULL, axial = TRUE, quiet = FALSE)
```

Arguments

x	numeric vector. Values in degrees
mu	The *a priori* expected direction (in degrees) for the alternative hypothesis.
w	numeric vector weights of length `length(x)`. If `NULL`, the non-weighted Rayleigh test is performed.
axial	logical. Whether the data are axial, i.e. π-periodical (`TRUE`, the default) or directional, i.e. 2π-periodical (`FALSE`).
quiet	logical. Prints the test's decision.

Details

The Null hypothesis is uniformity (randomness). The alternative is a distribution with a (specified) mean direction (`mu`). If `statistic >= p.value`, the null hypothesis of randomness is rejected and angles derive from a distribution with a (or the specified) mean direction.

Value

a list with the components:

R **or** C mean resultant length or the dispersion (if mu is specified). Small values of R (large values of C) will reject uniformity. Negative values of C indicate that vectors point in opposite directions (also lead to rejection).

statistic Test statistic

p.value significance level of the test statistic

weighting *Weighting Factors*

Description

Helper function to transform uncertainty angles into weighting factors

Usage

```
weighting(
  x,
  method = c("linear-inverse", "inverse", "cosine", "none"),
  max.err = 90
)
```

Arguments

x	numeric. Uncertainty angle in degrees.
method	character. One of "linear-inverse" (the default), "inverse", "cosine", or "none" (no transformation).
max.err	numeric. The maximum expected error for x (90 by default).

Details

Linear inverse: $w = 1 - x/\sigma$, where σ is the maximum error expected for x (e.g. $90°$).

Inverse: $w = 1/x$

Cosine: $w = \cos x$

Value

numeric

Examples

```
x <- seq(0, 90, 1)

plot(x, weighting(x, "inverse"),
  col = 1, type = "l",
  xlab = "Uncertainty angle in degrees", ylab = "weight"
)
lines(x, weighting(x, "cosine"), col = 2)
lines(x, weighting(x, "linear-inverse"), col = 3)
legend("topright",
  col = 1:3, lty = 1,
  legend = c("inverse", "cosine", "linear-inverse")
)
```
